The Different Kinds of Data

CS 5010 Program Design Paradigms
"Bootcamp"

Lesson 1.2

Learning Objectives for This Lesson

- By the time you finish this lesson, you should be able to:
  - explain the relationship between information and data.
  - define scalar, compound, and itemization data and give examples of each one.

Information and Data

Information → representation → Data

Data → interpretation → Information
Information Analysis and Data Design

- Information is what lives in the real world
- Need to decide *what part* of that information needs to be represented as data.
- Need to decide *how* that information will be represented as data
- Need to document how to *interpret* the data as information

Choosing a data representation

- Let's assume you know what pieces of information need to be represented.

- We need to know what kind of information each piece is.

Kinds of Data

Kinds of Data
1. Scalar Data
2. Compound Data
3. Itemization Data
4. Recursive Data
5. Mutually Recursive Data
6. Functional Data

1. Scalar Data

- Simple data, e.g. numbers, strings, etc.
- These are already values in Racket.
- Racket has lots more kinds of values, but these will be enough for now.
- If a variable or constant contains scalar data, the interpretation tells the meaning of that data.

2. Compound Data

- *Compound data* is data that consists of two or more quantities, or has two or more attributes
- Examples:
  - a book in a bookstore inventory
    - it has author, title, ISBN, cost, price
  - a circle on the screen
    - it has x and y positions, color, and radius.
- The interpretation gives the meaning of each field.

A Compound can contain a compound

- An author might have a first name, a last name, a birthdate, etc.

- A faucet might contain two washers
  - an upper washer and a lower washer

- Each washer might have several attributes
  - inner dimension, outer dimension, thickness
  - manufacturer, model number, cost, etc.

3. Itemization Data

- *Itemization data* is data that takes on one of a few alternative forms.

- Sometimes this is called "enumeration data."

- The data definition lists the possible forms and their interpretation.

Examples

```
;; A CupSize is represented as one of the
;; following integers:
;; -- 8, 12, 16, 20, 30
;; INTERP: the cup size, in fluid ounces

;; A TrafficLightState is represented as one of the
;; following strings:
;; -- "red"
;; -- "yellow"
;; -- "green"
;; INTERP: self-evident
```

One or more of the alternatives may be a compound

- In the textbook (HtDP/2e) this is called *mixed data*.

- This is just itemization data where one or more of the alternatives is a compound.

- This turns out to be a common situation.

Example

In a wine bar, an order may be one of three things: a cup of coffee, a glass of wine, or a cup of tea.

- – For the coffee, we need to specify the size (small, medium, or large) and type (this is a fancy bar, so it carries many types of coffee). Also whether or not it should be served with milk.

- – For the wine, we need to specify which vineyard and which year.

- – For tea, we need the size of the cup and the type of tea (this is a fancy bar, so it carries many types of tea).

Looking ahead

- In the next lesson, we'll learn how to write down your design in the form of a *data definition*.

Next Steps

- Do Guided Practice 1.1
- If you have questions about this lesson, ask them on the Discussion Board
- Go on to the next lesson
