Basics of Inheritance

CS 5010 Program Design Paradigms

"Bootcamp"

Lesson 12.1

Key Points for this Module

- Inheritance is a technique for generalizing over common parts of class implementations.
- When we create such a generalization, we specialize by subclassing.
- Languages with inheritance have many new design choices.

Key Points for Lesson 12.1

- By the end of this lesson you should be able to explain how objects find methods by searching up the inheritance chain.
- Use the overriding-defaults pattern to introduce small variations of a class.

Example: flashing-balls

- Sometimes we want to define a new class that is just a small variation of an old class.
- For example, we might want to make a ball that flashes different colors.
- To do this, create a subclass that inherits from the old class (the "superclass").
- We call this the "overriding defaults" pattern.
- Let's look at a demonstration.

Video demo: flashing-balls.rkt

- http://youtu.be/YX5iFECva1I (7:56)

Features for Inheritance in Racket

- The Racket object system uses two features to implement inheritance: **define/override** and **inherit-fields**.
  - **`define/override`** is used to define methods that override methods in the superclass.
  - **`inherit-fields`** is used to declare fields of the superclass that we want to make visible in the subclass.
    - eg: x, y, selected?, radius in **`FlashingBall%`**.
    - values are automatically supplied to the superclass on initialization.

Other languages do this differently, so watch out!

What fields are in the subclass?

- The init-fields of a subclass are the init-fields of the superclass plus any additional init-fields declared in the subclass.
- FlashingBall% doesn't declare any new init-fields, so its init-fields are the same as those of Ball%.
- init-fields of the subclass are automatically sent to the superclass, so when we create a FlashingBall%, we write

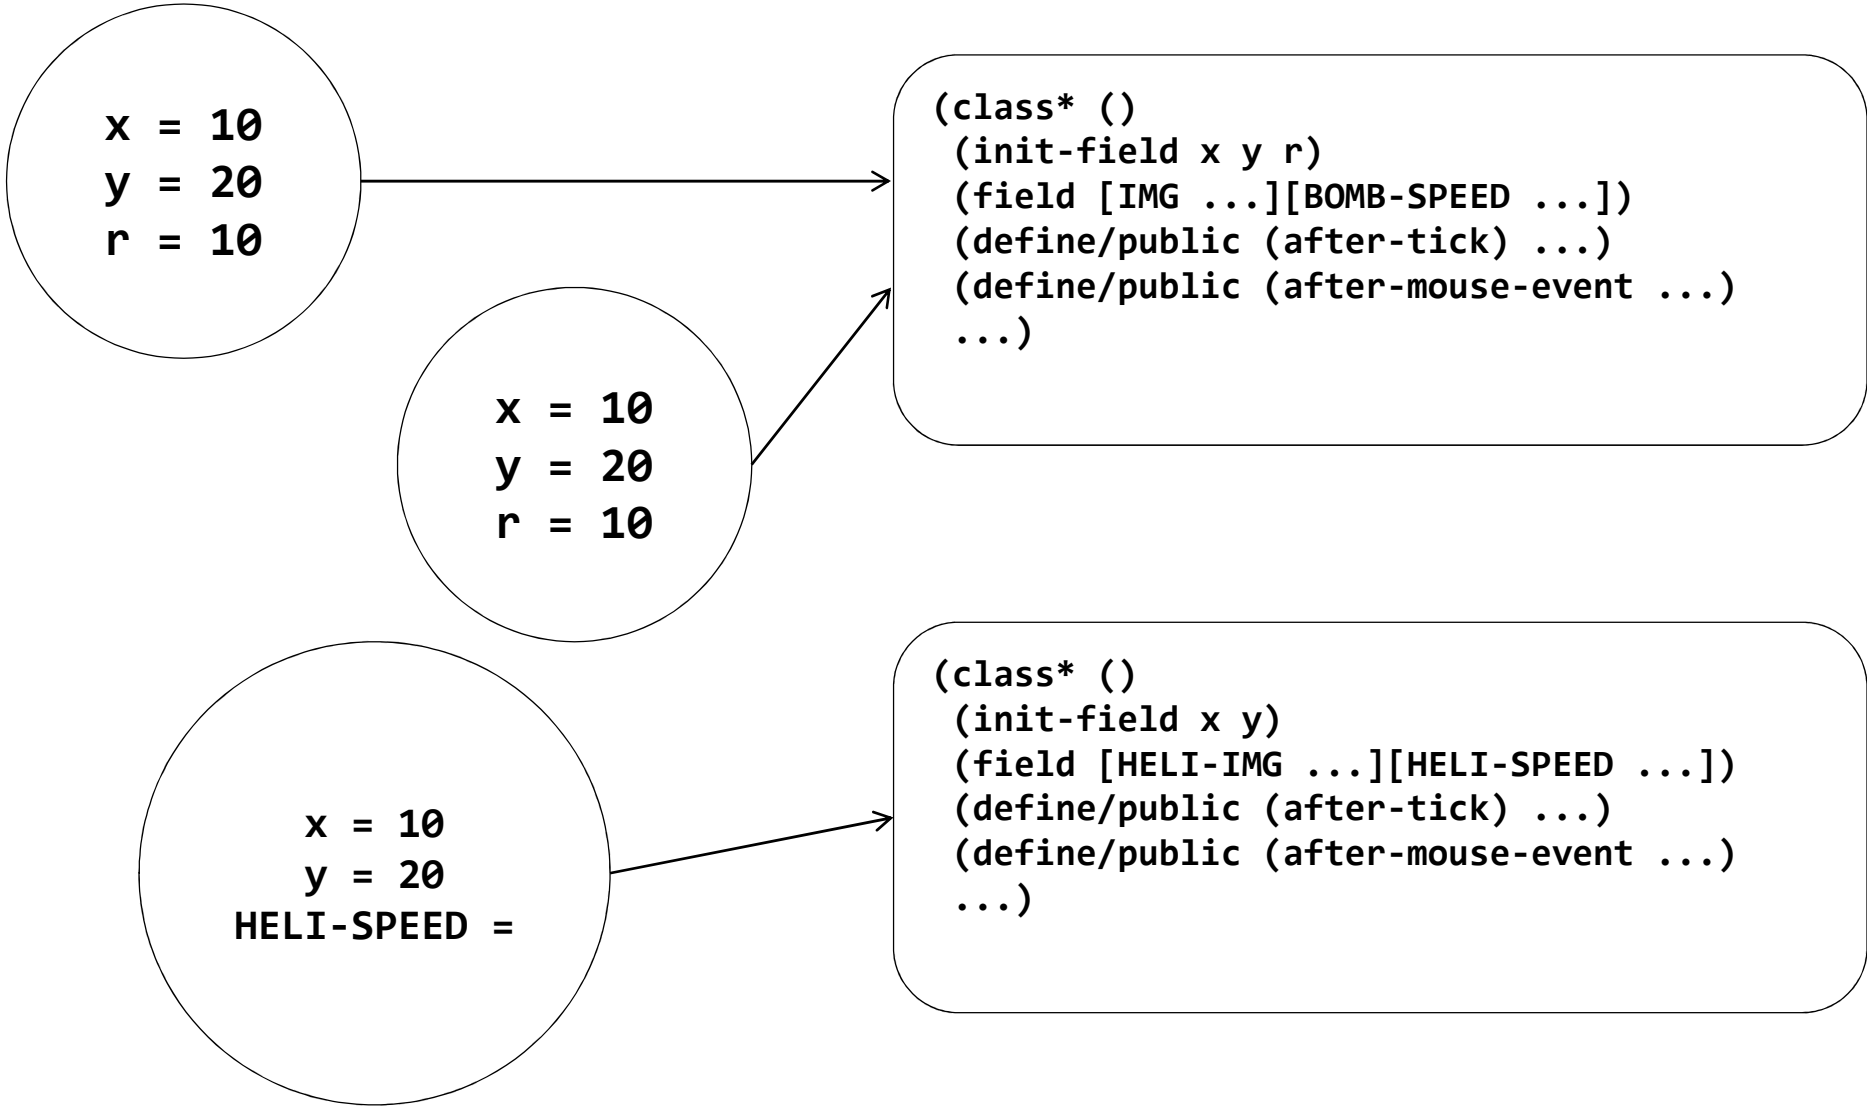
```
(new FlashingBall% [x ...][y ...][box ...][speed ...])
```

- Those values become the values for the fields in Ball%, so they can be used by the methods in Ball%.
- x and y are also inherited fields, so they are visible to the methods in FlashingBall% as well.

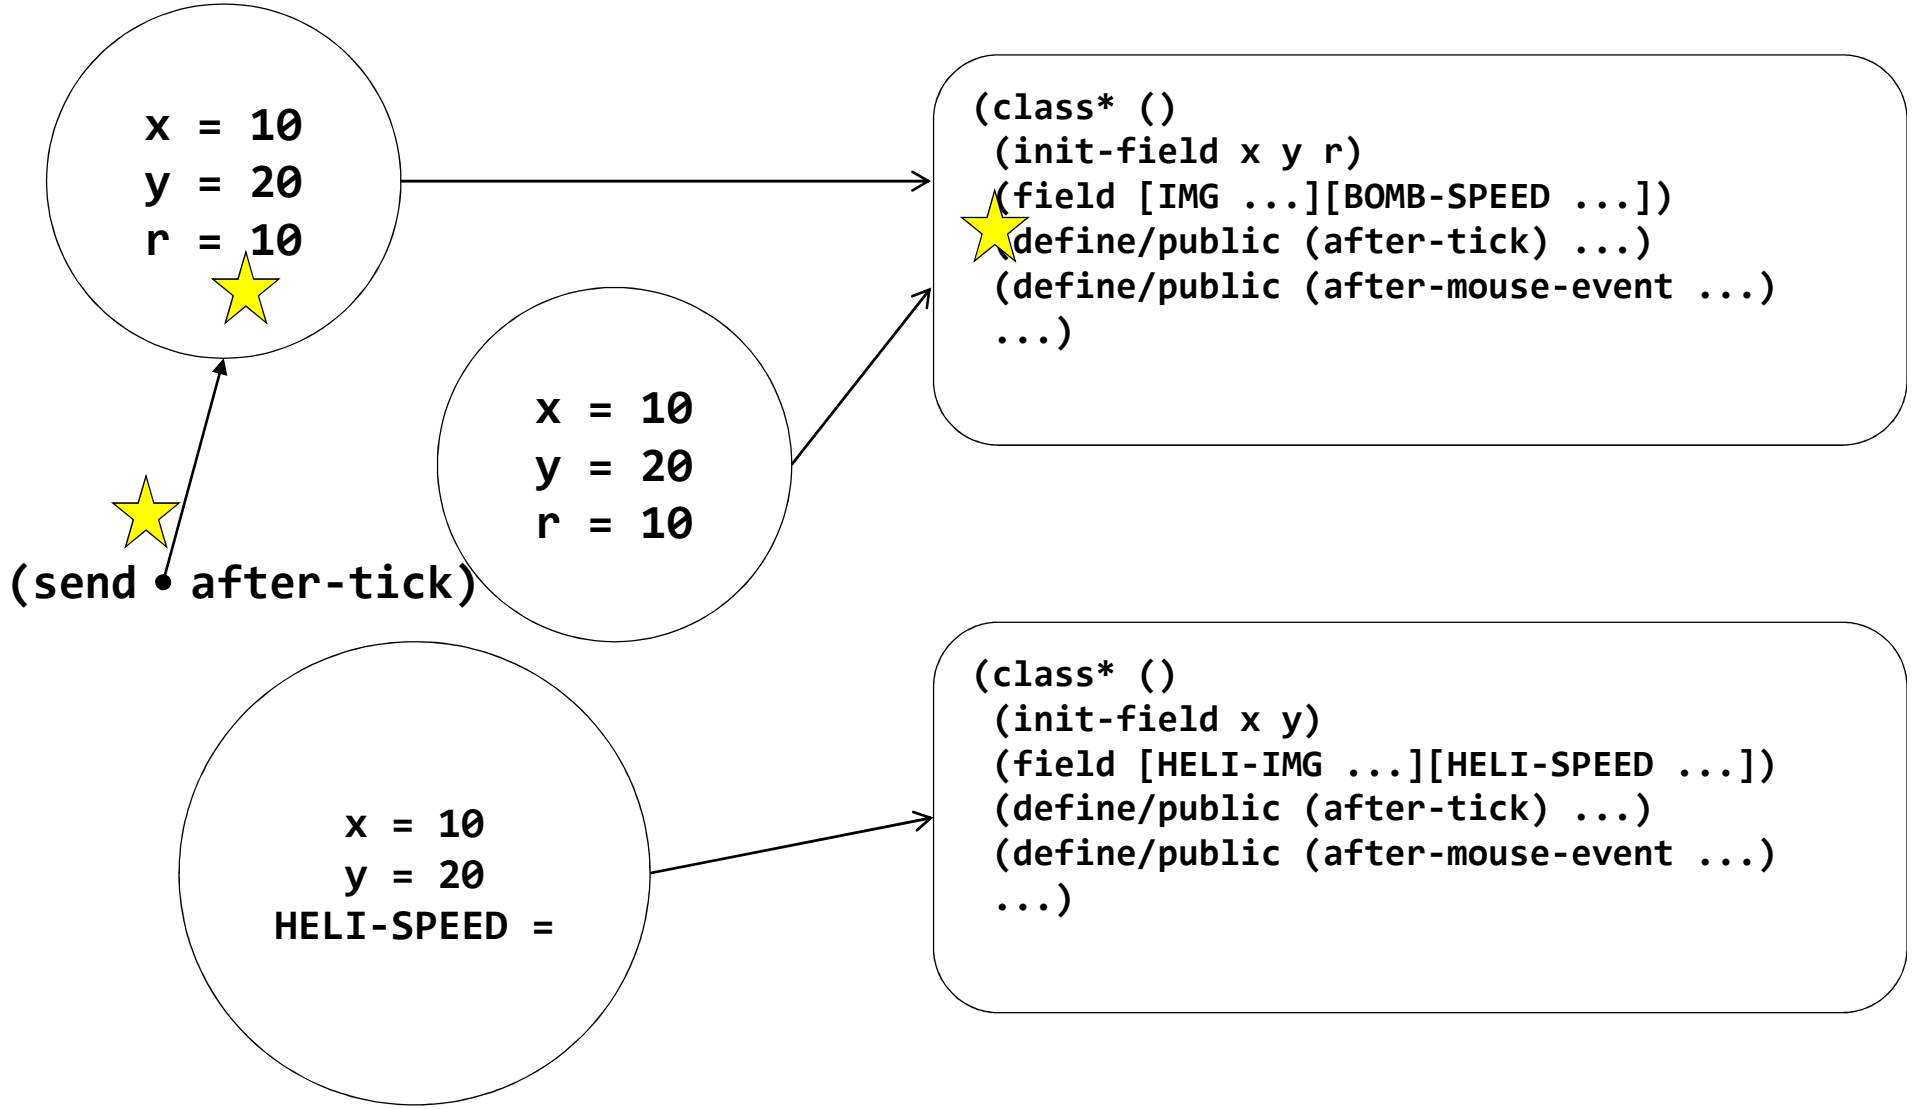
Video Demonstration: How inheritance works

- http://youtu.be/GifYzTiD7X4 (2:23)
- The next few slides are the ones from the video. Be sure to watch them as a Slide Show, so you can see the animation.

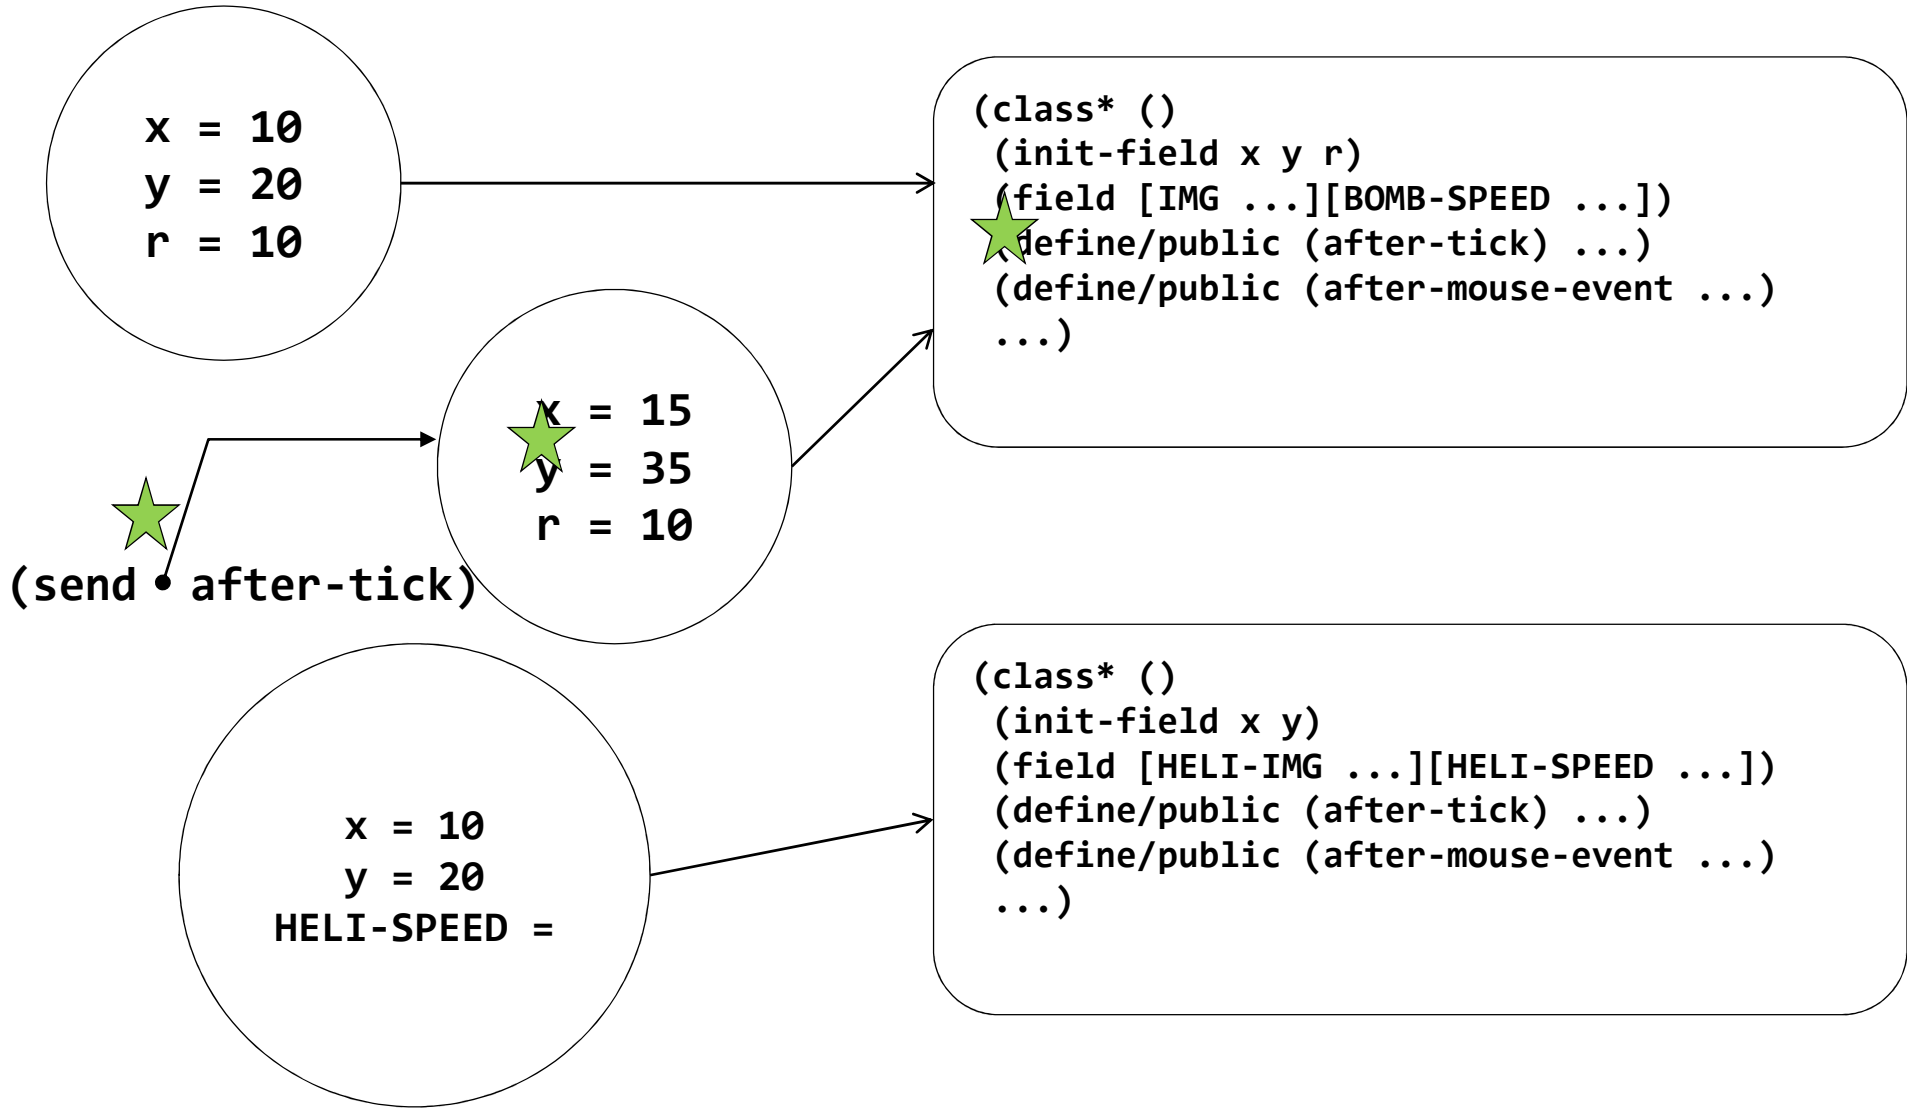
Review: Every object knows its class



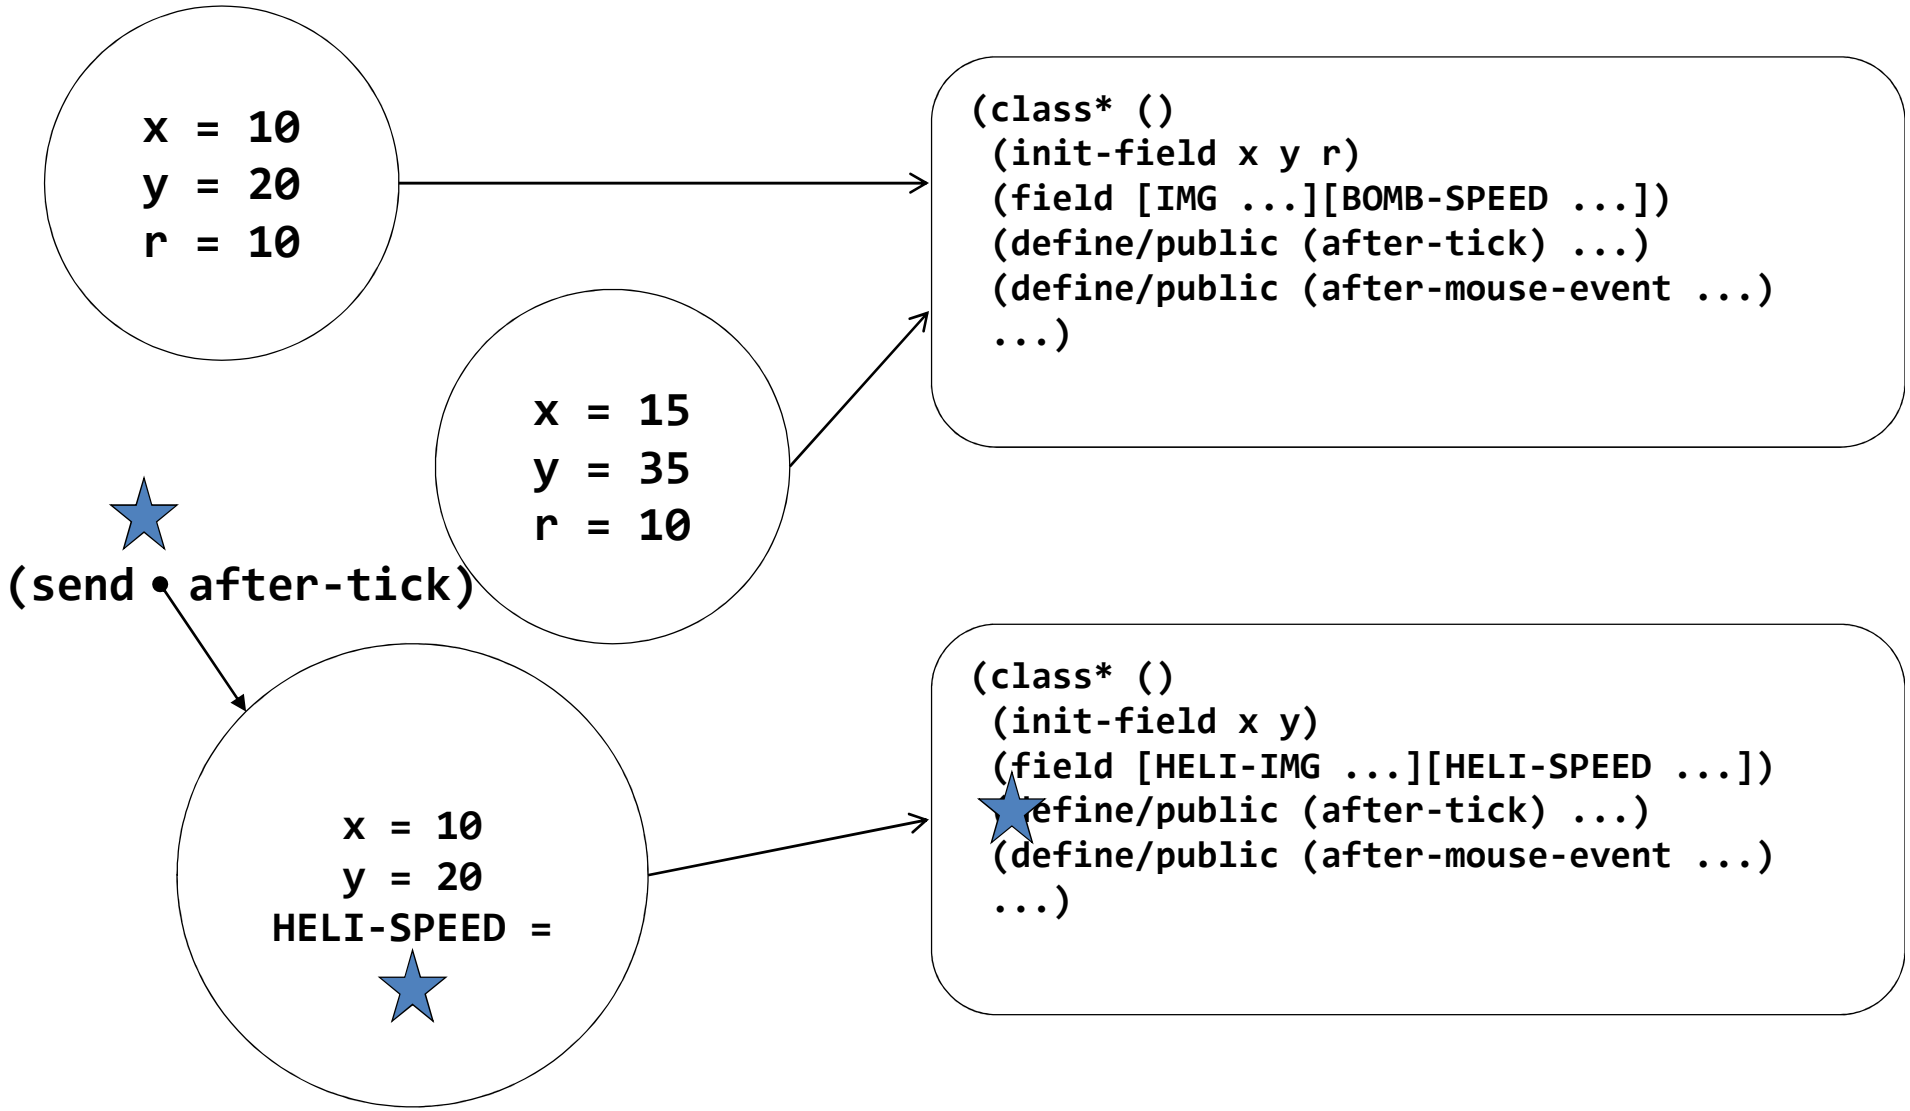
Review: Every object knows its class



Every object knows its class



Every object knows its class



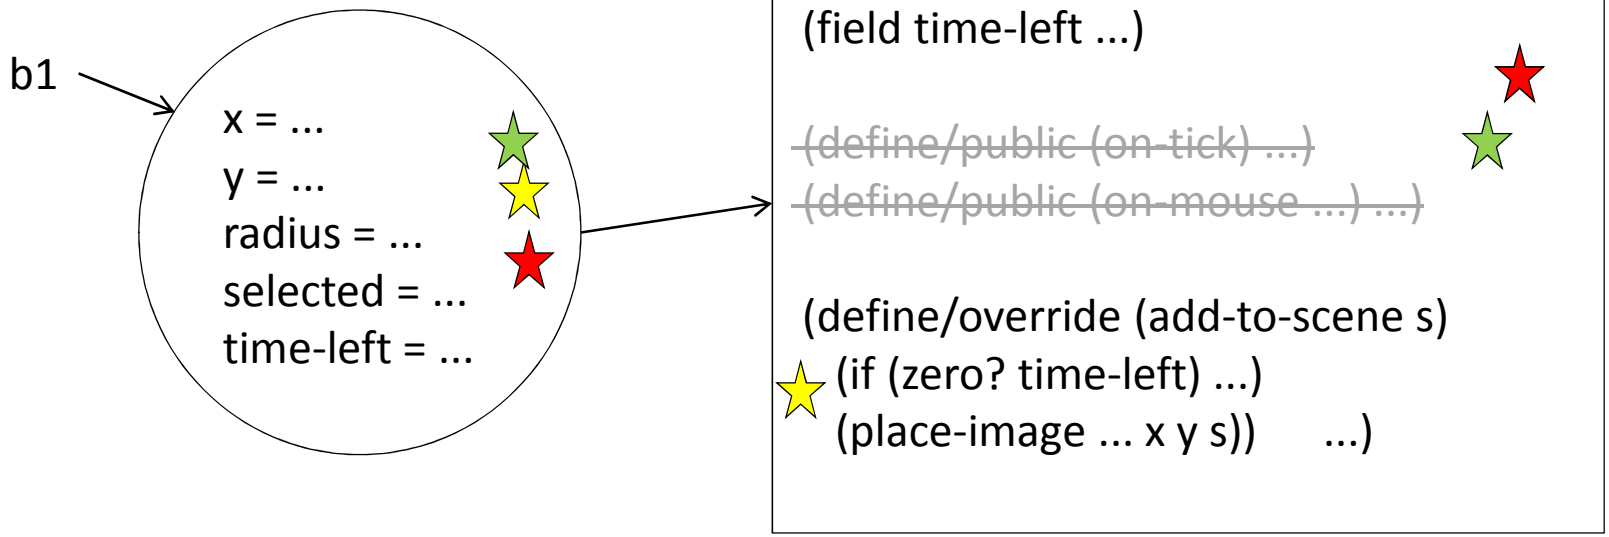
An object searches its inheritance chain for a suitable method

(define b1 (new FlashingBall% ...))

(send b1 add-to-scene s)

(send b1 on-tick)

(send b1 launch-missiles)



The overriding-defaults pattern

The flashing ball was an example of the *overriding-defaults* pattern. In the overriding-defaults pattern:

- The superclass has a complete set of behaviors
- The subclass makes an incremental change in these behaviors by overriding some of them.

Inheritance and **this**

- If a method in the superclass refers to **this**, where do you look for the method?
- Answer: in the original object.
- Consider the following class hierarchy:

Searching for a method of **this**

```
(define b1 (new FlashingBall% ...))
(send b1 m1 33)
```

When we send **b1** an **m1** message, what happens?

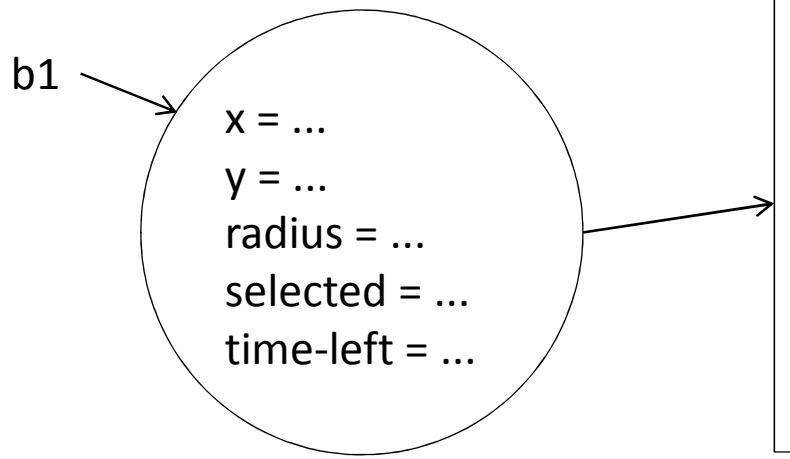
1) It searches its own methods for an **m1** method, and finds none.
2) It searches it superclass for an **m1** method. This time it finds one, which says to send **this** an **m2** message.
3) **this** still refers to **b1**. So **b1** starts searching for an **m2** method.
4) It finds the m2 method in its local table, and returns the string "right".

```
Ball% = (class* object% ()
 (field x y radius selected?)
 (define/public (m1 x) (send this m2 x))
 (define/public (m2 x) "wrong")

 )
```

```
FlashingBall% = (class* Ball% ()

(define/override (m2 x) "right")
...)
```



super

- Sometimes the subclass doesn't need to change the behavior of the superclass's method; instead it just needs to add behavior to the existing method.
- **(super** *method args* …**)** calls the method named method in the superclass of the class in which the method is defined.

Use case for **super**

```
(define the-superclass%
  (class* object% ()
   (define/public (m1 x)
     (... big-hairy function of x ...))))

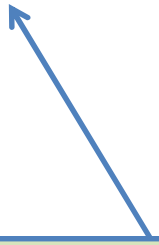
(define the-subclass%
  (class* the-superclass% ()
    (define/public (m1 x)
      (... Same big hairy function,
           but now of x+1 ...))))
```

We don't want to have to write out the big hairy function again. Can we avoid this repeated code?

Use case for **super**

```
(define the-superclass%
  (class* object% ()
   (define/public (m1 x)
     (... big-hairy function of x ...))))

(define the-subclass%
  (class* the-superclass% ()
    (define/public (m1 x)
      (super m1 (+ x 1)))))
```



This calls m1 in the superclass.

You can call any method in the **super**

```
(define the-superclass%
  (class* object% ()
   (define/public (m1 x)
     (... big-hairy function of x ...))))

(define the-subclass%
  (class* the-superclass% ()
    (define/public (m2 x)
      (super m1 (+ x 1)))))
```

Here method **m2** in the subclass calls method **m1** in the superclass.

this and **super**, summarized

- The rules for this and super can be summarized as:

  this is dynamic, **super** is static

- This simple rule can lead to interesting behavior
  - Do GP 12.1 and 12.2 to learn more about this.
- We will take great advantage of the dynamic nature of **this** in the next lesson.

Summary of Lesson 12.1

- We've seen how to define superclasses and subclasses in Racket, including **inherit-field** and **define/override**.
- We've seen the overriding-defaults pattern, in which a subclass overrides some methods of a complete superclass
- We learned how **this** works with inheritance, and what **super** does.
