

# Machine Translation

Natural Language Processing  
CS 6120—Spring 2013  
Northeastern University

David Smith  
some slides from  
Charles Schafer & Philip Koehn

# Translation and NLP

- Translation is one of the oldest language tasks tried on a computer
  - Just look at that archaic name: “Machine Translation”!
- Translation involves many linguistic systems
- “Apollo program” dual-use argument:
  - Translation models of alignment and transfer are useful in question answering, paraphrase, information retrieval, etc.

# Overview

- What problems does MT address? What does it (currently) not address?
- Models: What makes a good translation?
- Alignment: Learning dictionaries from parallel text
- Next: non-parallel text, translation decoding and training

# The Translation Problem and Translation Data

## The Translation Problem

মানব পরিবারের সকল সদস্যের সমান ও অবিচ্ছেদ্য অধিকারসমূহ  
এবং সহজাত মর্যাদার স্বীকৃতিই হচ্ছে বিশ্বে শান্তি, স্বাধীনতা এবং  
ন্যায়বিচারের ভিত্তি

## The Translation Problem

মানব পরিবারের সকল সদস্যের সমান ও অবিচ্ছেদ্য অধিকারসমূহ  
এবং সহজাত মর্যাদার স্বীকৃতিই হচ্ছে বিশ্বে শান্তি, স্বাধীনতা এবং  
ন্যায়বিচারের ভিত্তি

## The Translation Problem

মানব পরিবারের সকল সদস্যের সমান ও অবিচ্ছেদ্য অধিকারসমূহ  
এবং সহজাত মর্যাদার স্বীকৃতিই হচ্ছে বিশ্বে শান্তি, স্বাধীনতা এবং  
ন্যায়বিচারের ভিত্তি

Whereas recognition of the inherent dignity and of the  
equal and inalienable rights of all members of the  
human family is the foundation of freedom, justice and  
peace in the world

## Why Machine Translation?

\* **Cheap**, universal access to world's **online** information regardless of original language.  
(That's the goal)

## Why Statistical (or at least Empirical) Machine Translation?

\* We want to translate **real-world** documents.  
Thus, we should **model** real-world documents.

\* A nice property: design the system once, and extend to new languages automatically by training on existing data.

$F(\text{training data}, \text{model}) \rightarrow$  parameterized MT system

## Ideas that cut across empirical language processing problems and methods

**Real-world:** don't be (too) prescriptive. Be able to process (translate/summarize/identify/paraphrase) relevant bits of human language as they are, not as they "should be". For instance, genre is important: translating French blogs into English is different from translating French novels into English.

**Model:** a fully described procedure, generally having variable parameters, that performs some interesting task (for example, translation).

**Training data:** a set of observed data instances which can be used to find good parameters for a model via a training procedure.

**Training procedure:** a method that takes observed data and refines the parameters of a model, such that the model is improved according to some objective function.

# Resource Availability

Most of this lecture

Most statistical machine translation (SMT) research has focused on a few "high-resource" languages (European, Chinese, Japanese, Arabic).

Some other work: translation for the rest of the world's languages found on the web.

Most statistical machine translation research has focused on a few high-resource languages (European, Chinese, Japanese, Arabic).

Approximate Parallel Text Available (with English)

(~200M words)

## Resource Availability

Most statistical machine translation (SMT) research has focused on a few "high-resource" languages (European, Chinese, Japanese, Arabic).

Some other work: translation for the rest of the world's languages found on the web.

Romanian Catalan Serbian Slovenian Macedonian Uzbek Turkmen Kyrgyz Uighur  
Pashto Tajik Dari Kurdish Azeri Bengali Punjabi Gujarati Nepali Urdu  
Marathi Konkani Oriya Telugu Malayalam Kannada Cebuano

We'll discuss this briefly

# The Translation Problem

Document translation? Sentence translation? Word translation?

What to translate? The most common use case is probably document translation.

Most MT work focuses on sentence translation.

What does sentence translation ignore?

- Discourse properties/structure.
- Inter-sentence coreference.

# Sentence Translation

- SMT has generally ignored extra-sentence structure (good future work direction for the community).
- Instead, we've concentrated on translating individual sentences as well as possible. This is a very hard problem in itself.
- Word translation (knowing the possible English translations of a French word) is not, by itself, sufficient for building readable/useful automatic document translations - though it is an important component in end-to-end SMT systems.

*Sentence translation using only a word translation dictionary is called "glossing" or "gisting".*

## Word Translation (learning from minimal resources)

We'll come back to this later..

and address learning the word translation component (dictionary) of MT systems without using parallel text.

(For languages having little parallel text, this is the best we can do right now)

## Sentence Translation

- Training resource: parallel text (bitext).
- Parallel text (with English) on the order of 20M-200M words (roughly, 1M-10M sentences) is available for a number of languages.
- Parallel text is expensive to generate: human translators are expensive (\$0.05-\$0.25 per word). Millions of words training data needed for high quality SMT results. So we take what is available. This is often of less than optimal genre (laws, parliamentary proceedings, religious texts).

# Sentence Translation: examples of more and less literal translations in bitext

French, English from Bitext

---

Closely Literal English Translation

---

**Le débat est clos .  
The debate is closed .**

*The debate is closed.*

**Accepteriez - vous ce principe ?  
Would you accept that principle ?**

*Accept-you that principle?*

**Merci , chère collègue .  
Thank you , Mrs Marinucci .**

*Thank you, dear colleague.*

**Avez - vous donc une autre proposition ?  
Can you explain ?**

*Have you therefore another proposal?*

(from French-English European Parliament proceedings)

# Sentence Translation: examples of more and less literal translations in bitext

Word alignments illustrated.  
Well-defined for more literal translations.

**Le débat est clos .**

**The debate is closed .**

**Accepteriez - vous ce principe ?**

**Would you accept that principle ?**

**Merci , chère collègue .**

**Thank you , Mrs Marinucci .**

**Avez - vous donc une autre proposition ?**

**Can you explain ?**

## Translation and Alignment

- As mentioned, translations are expensive to commission and generally SMT research relies on already existing translations
- These typically come in the form of aligned documents.
- A sentence alignment, using pre-existing document boundaries, is performed automatically. Low-scoring or non-one-to-one sentence alignments are discarded. The resulting aligned sentences constitute the training bitext.
- For many modern SMT systems, induction of word alignments between aligned sentences, using algorithms based on the IBM word-based translation models, is one of the first stages of processing. Such induced word alignments are generally treated as part of the observed data and are used to extract aligned phrases or subtrees.

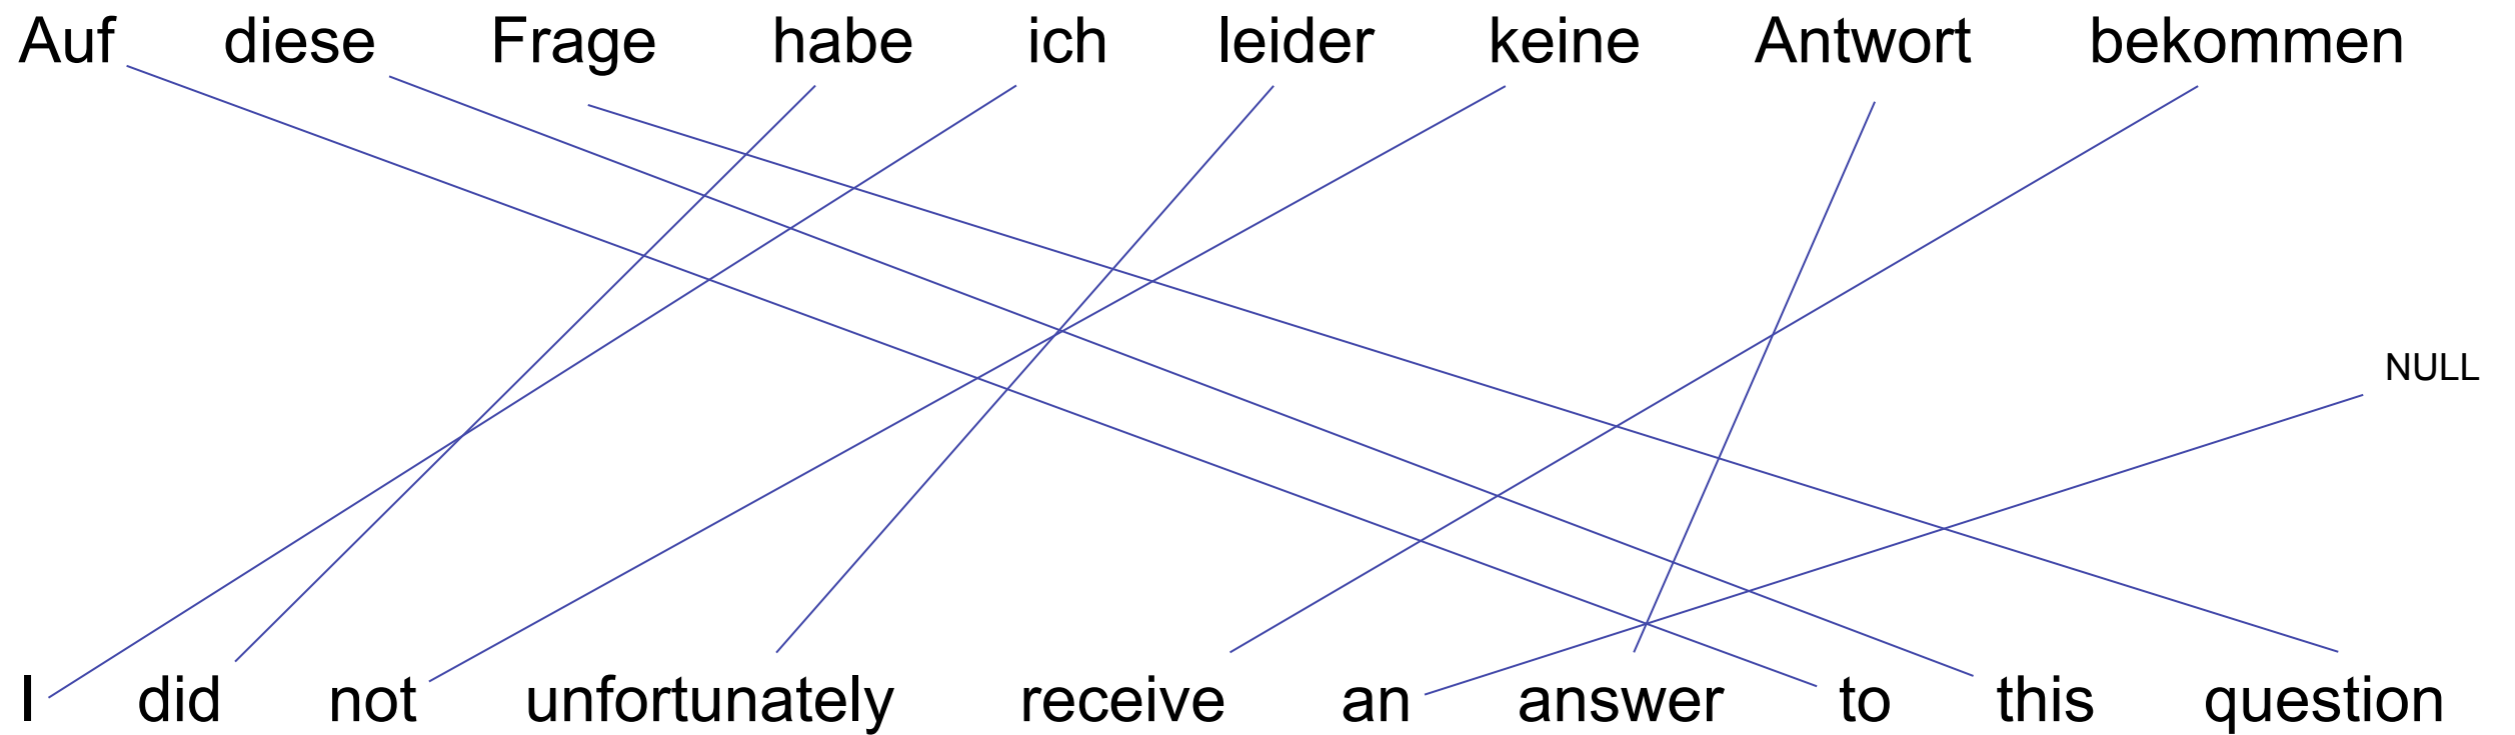

# Modeling

What Makes a Good Translation?

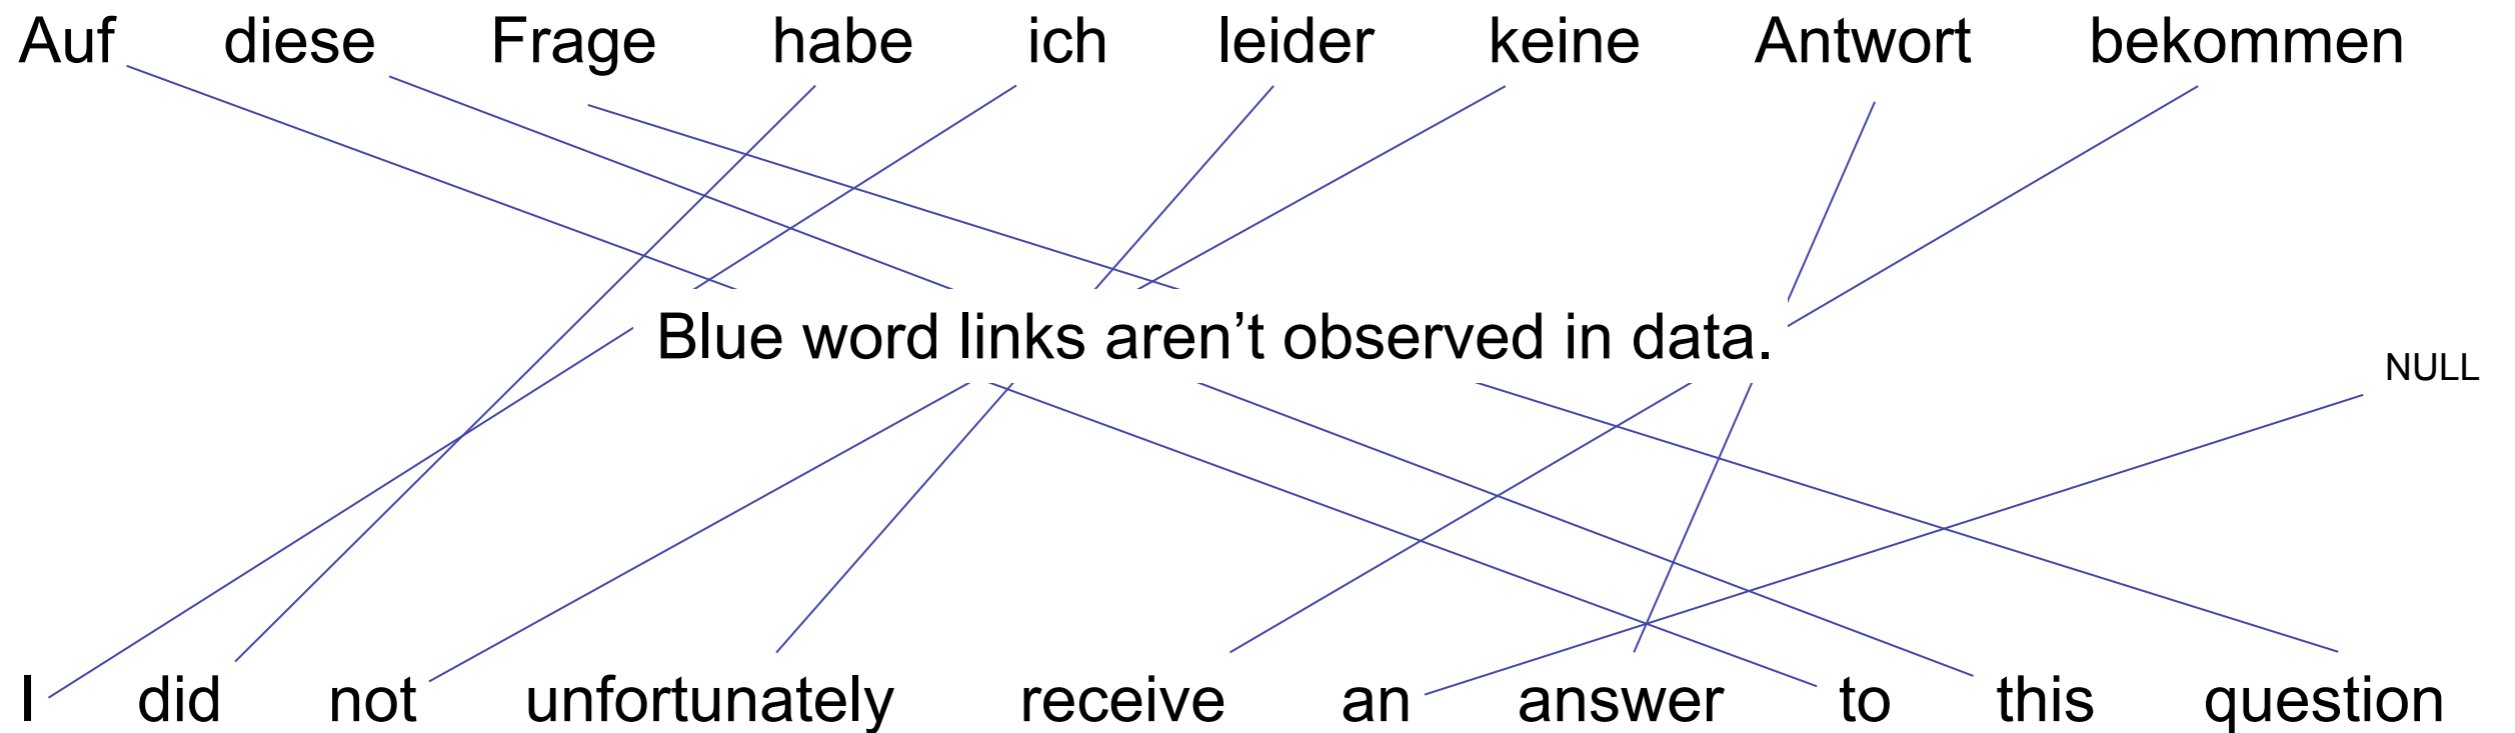

# Modeling

- Translation models
  - “Adequacy”
  - Assign better scores to accurate (and complete) translations
- Language models
  - “Fluency”
  - Assign better scores to natural target language text

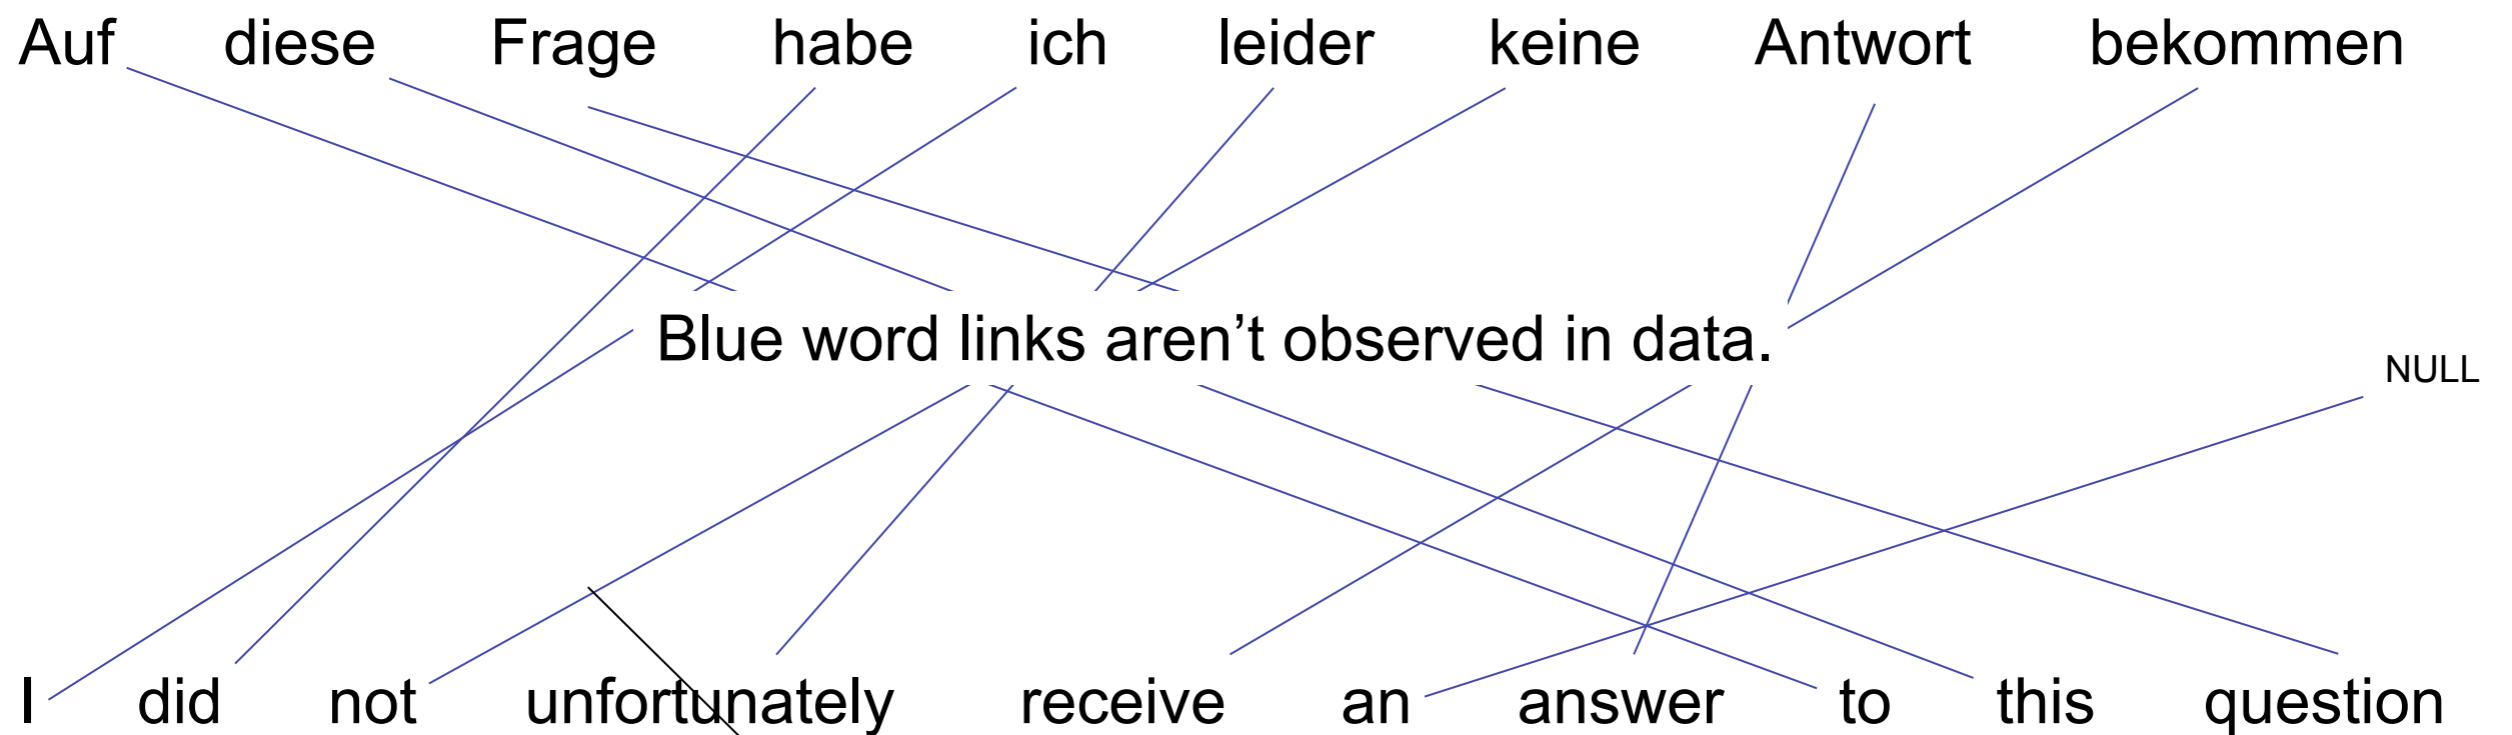

# Word Translation Models

# Word Translation Models

# Word Translation Models

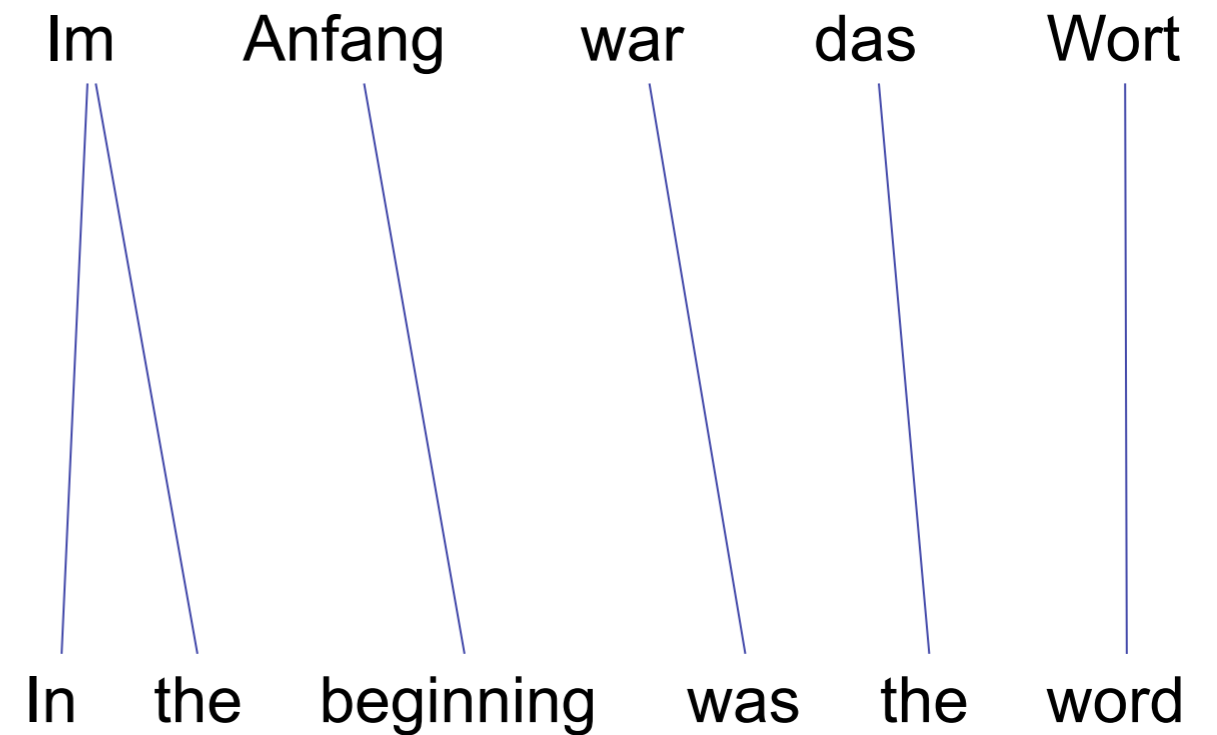

Features for word-word links: lexica, part-of-speech, orthography, etc.

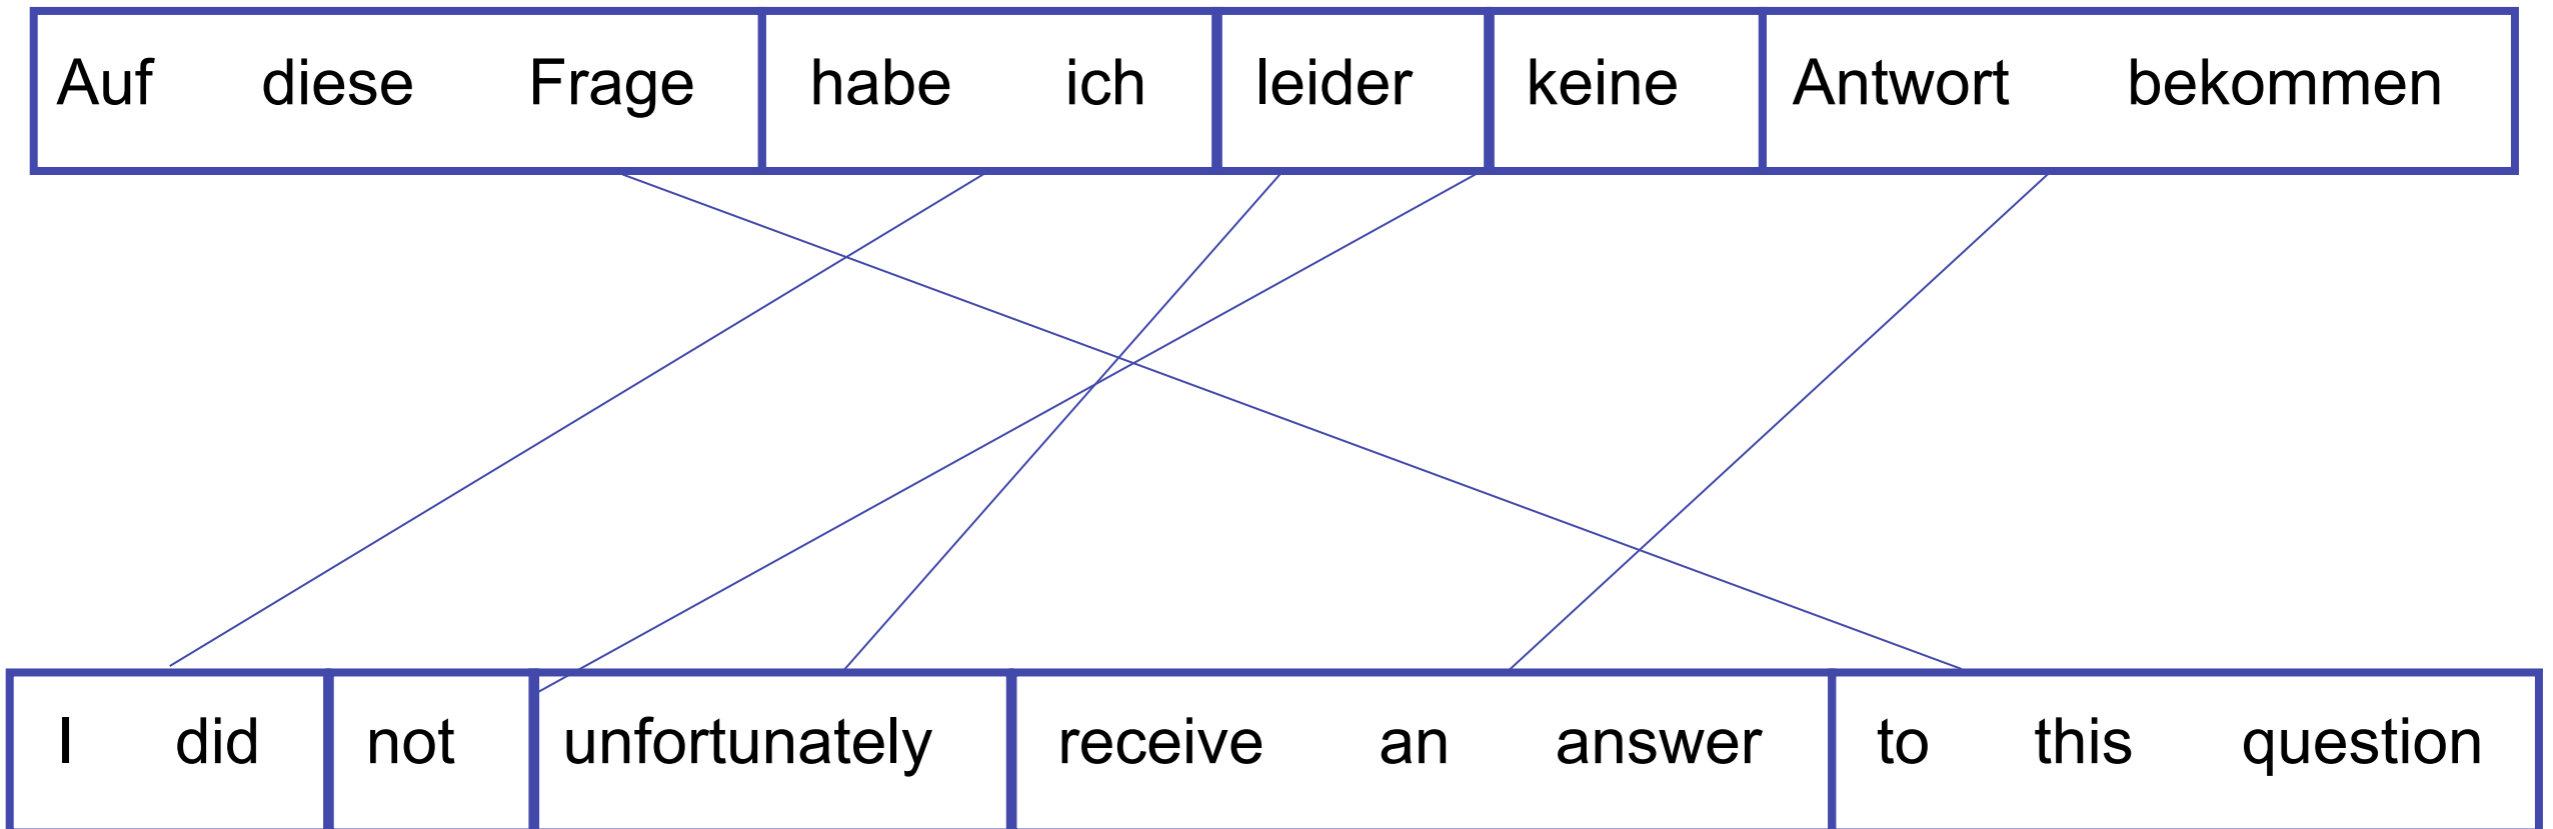

# Word Translation Models

- Usually directed: each word in the target generated by one word in the source
- Many-many and null-many links allowed
- Classic IBM models of Brown et al.
- Used now mostly for word alignment, not translation

# Phrase Translation Models

# Phrase Translation Models

Not necessarily syntactic phrases

Auf	diese	Frage	habe	ich	leider	keine	Antwort	bekommen

---	-----	-----	---------------	---------	----	--------	----	------	----------

Score each phrase pair using several features

# Phrase Translation Models

Not necessarily syntactic phrases

Division into phrases is hidden

Auf diese Frage habe ich leider keine Antwort bekommen

phrase= 0.212121, 0.0550809; lex= 0.0472973, 0.0260183; lcount=2.718  
What are some other features?

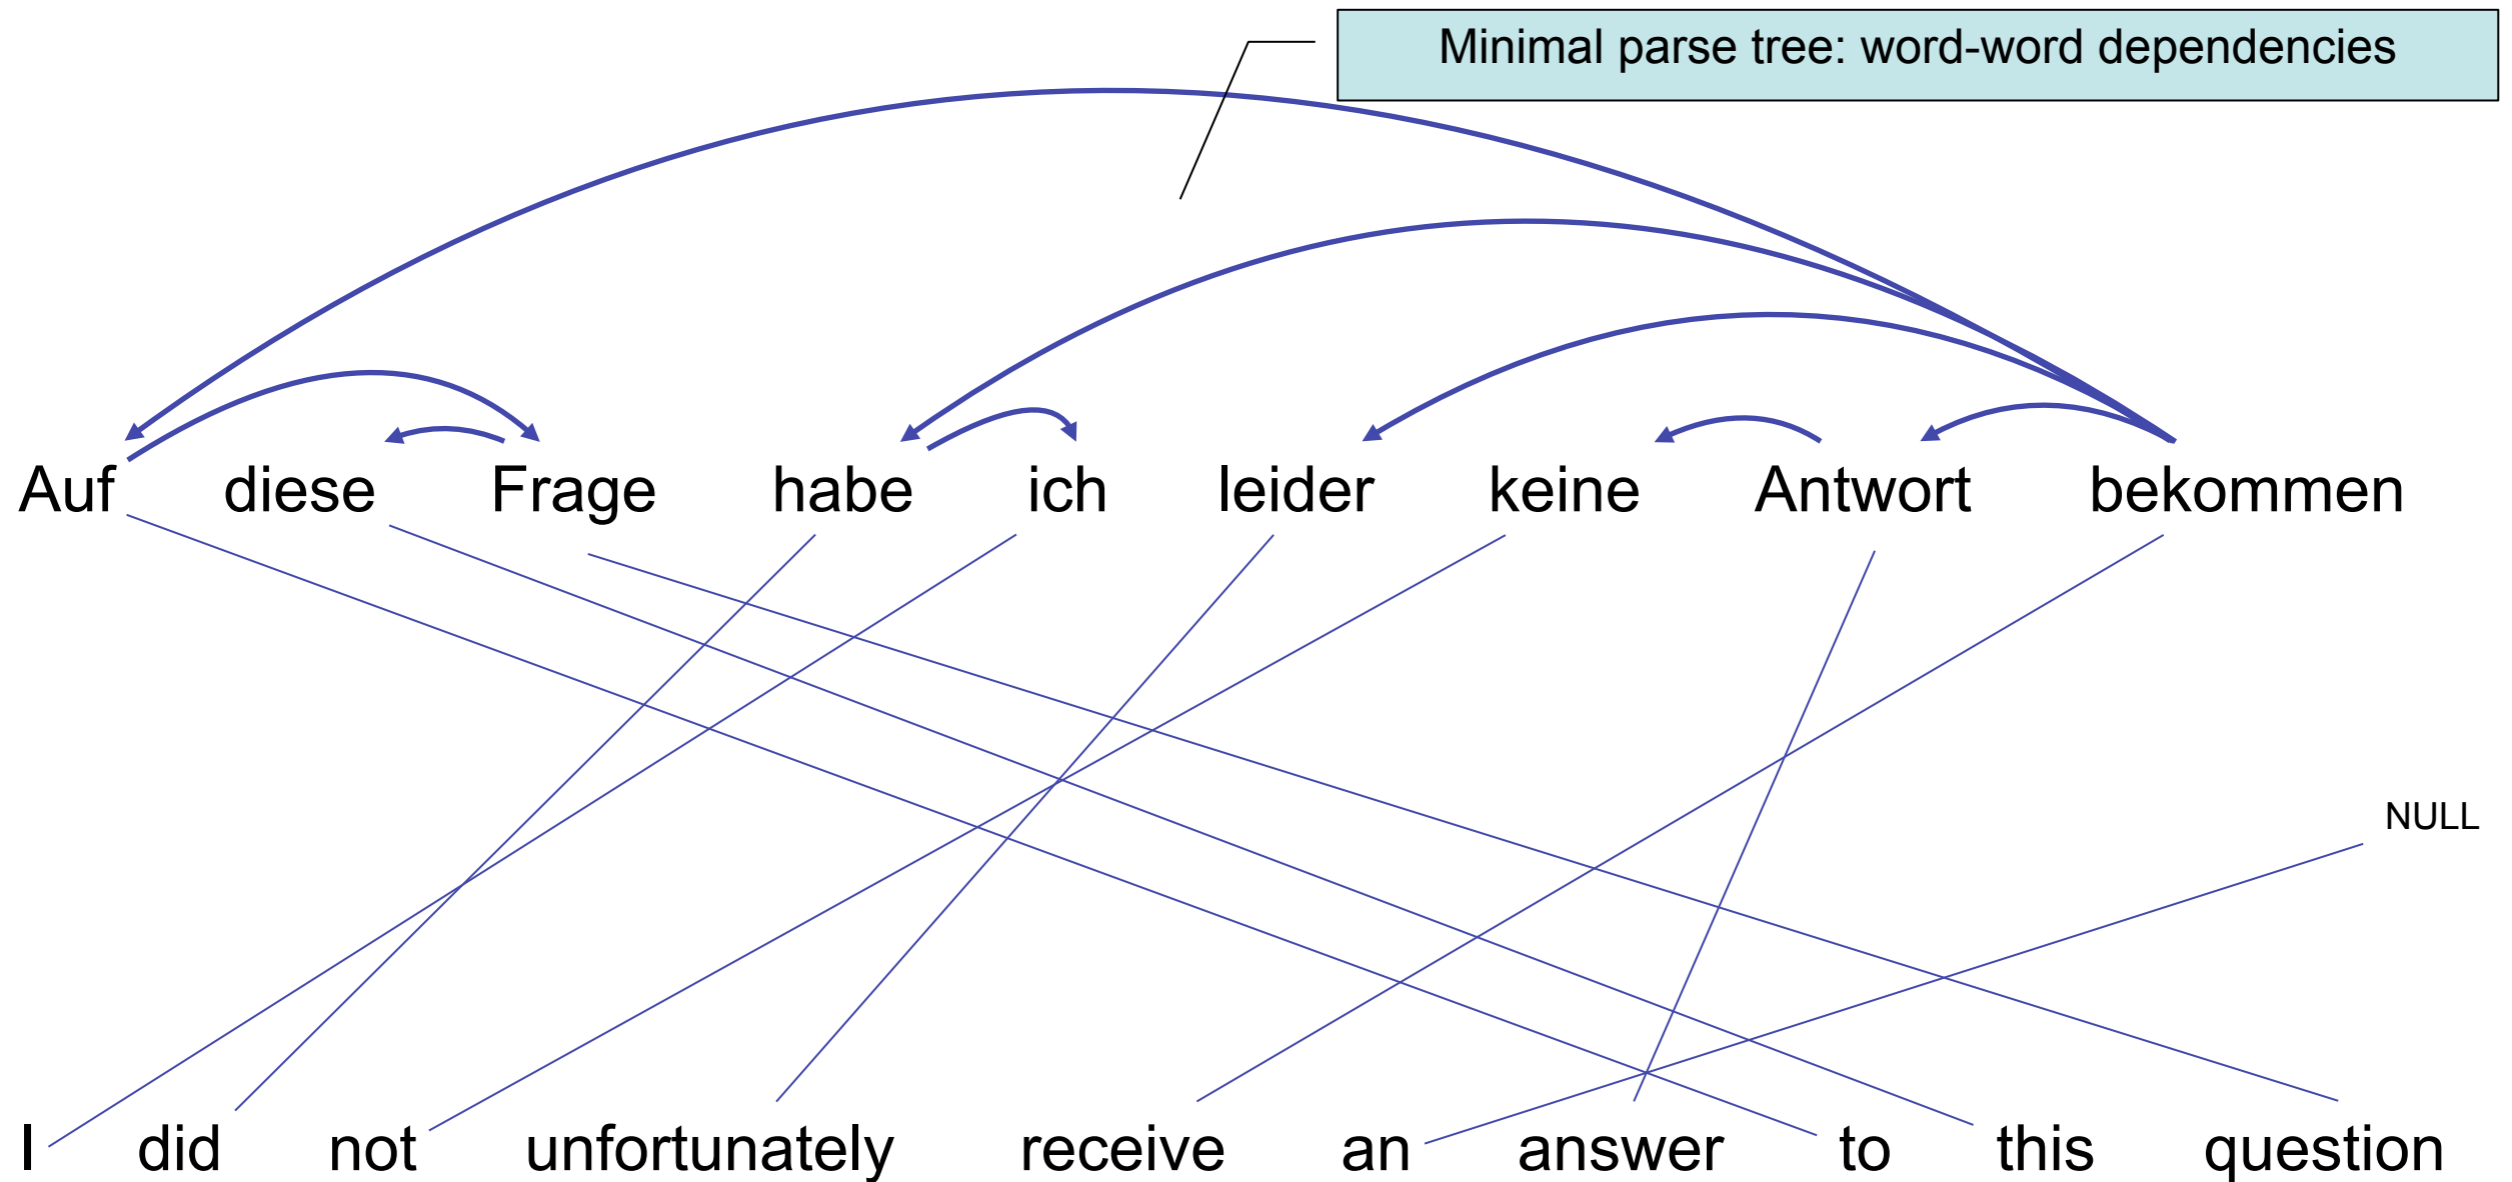

I did not unfortunately receive an answer to this question

Score each phrase pair using several features

# Phrase Translation Models

- Capture translations **in context**
  - *en Amerique*: **to** America
  - *en anglais*: **in** English
- State-of-the-art for several years
- Each source/target phrase pair is scored by several weighted features.
- The weighted sum of model features is the whole translation's score.
- Phrases don't overlap (cf. language models) but have "reordering" features.

# Single-Tree Translation Models

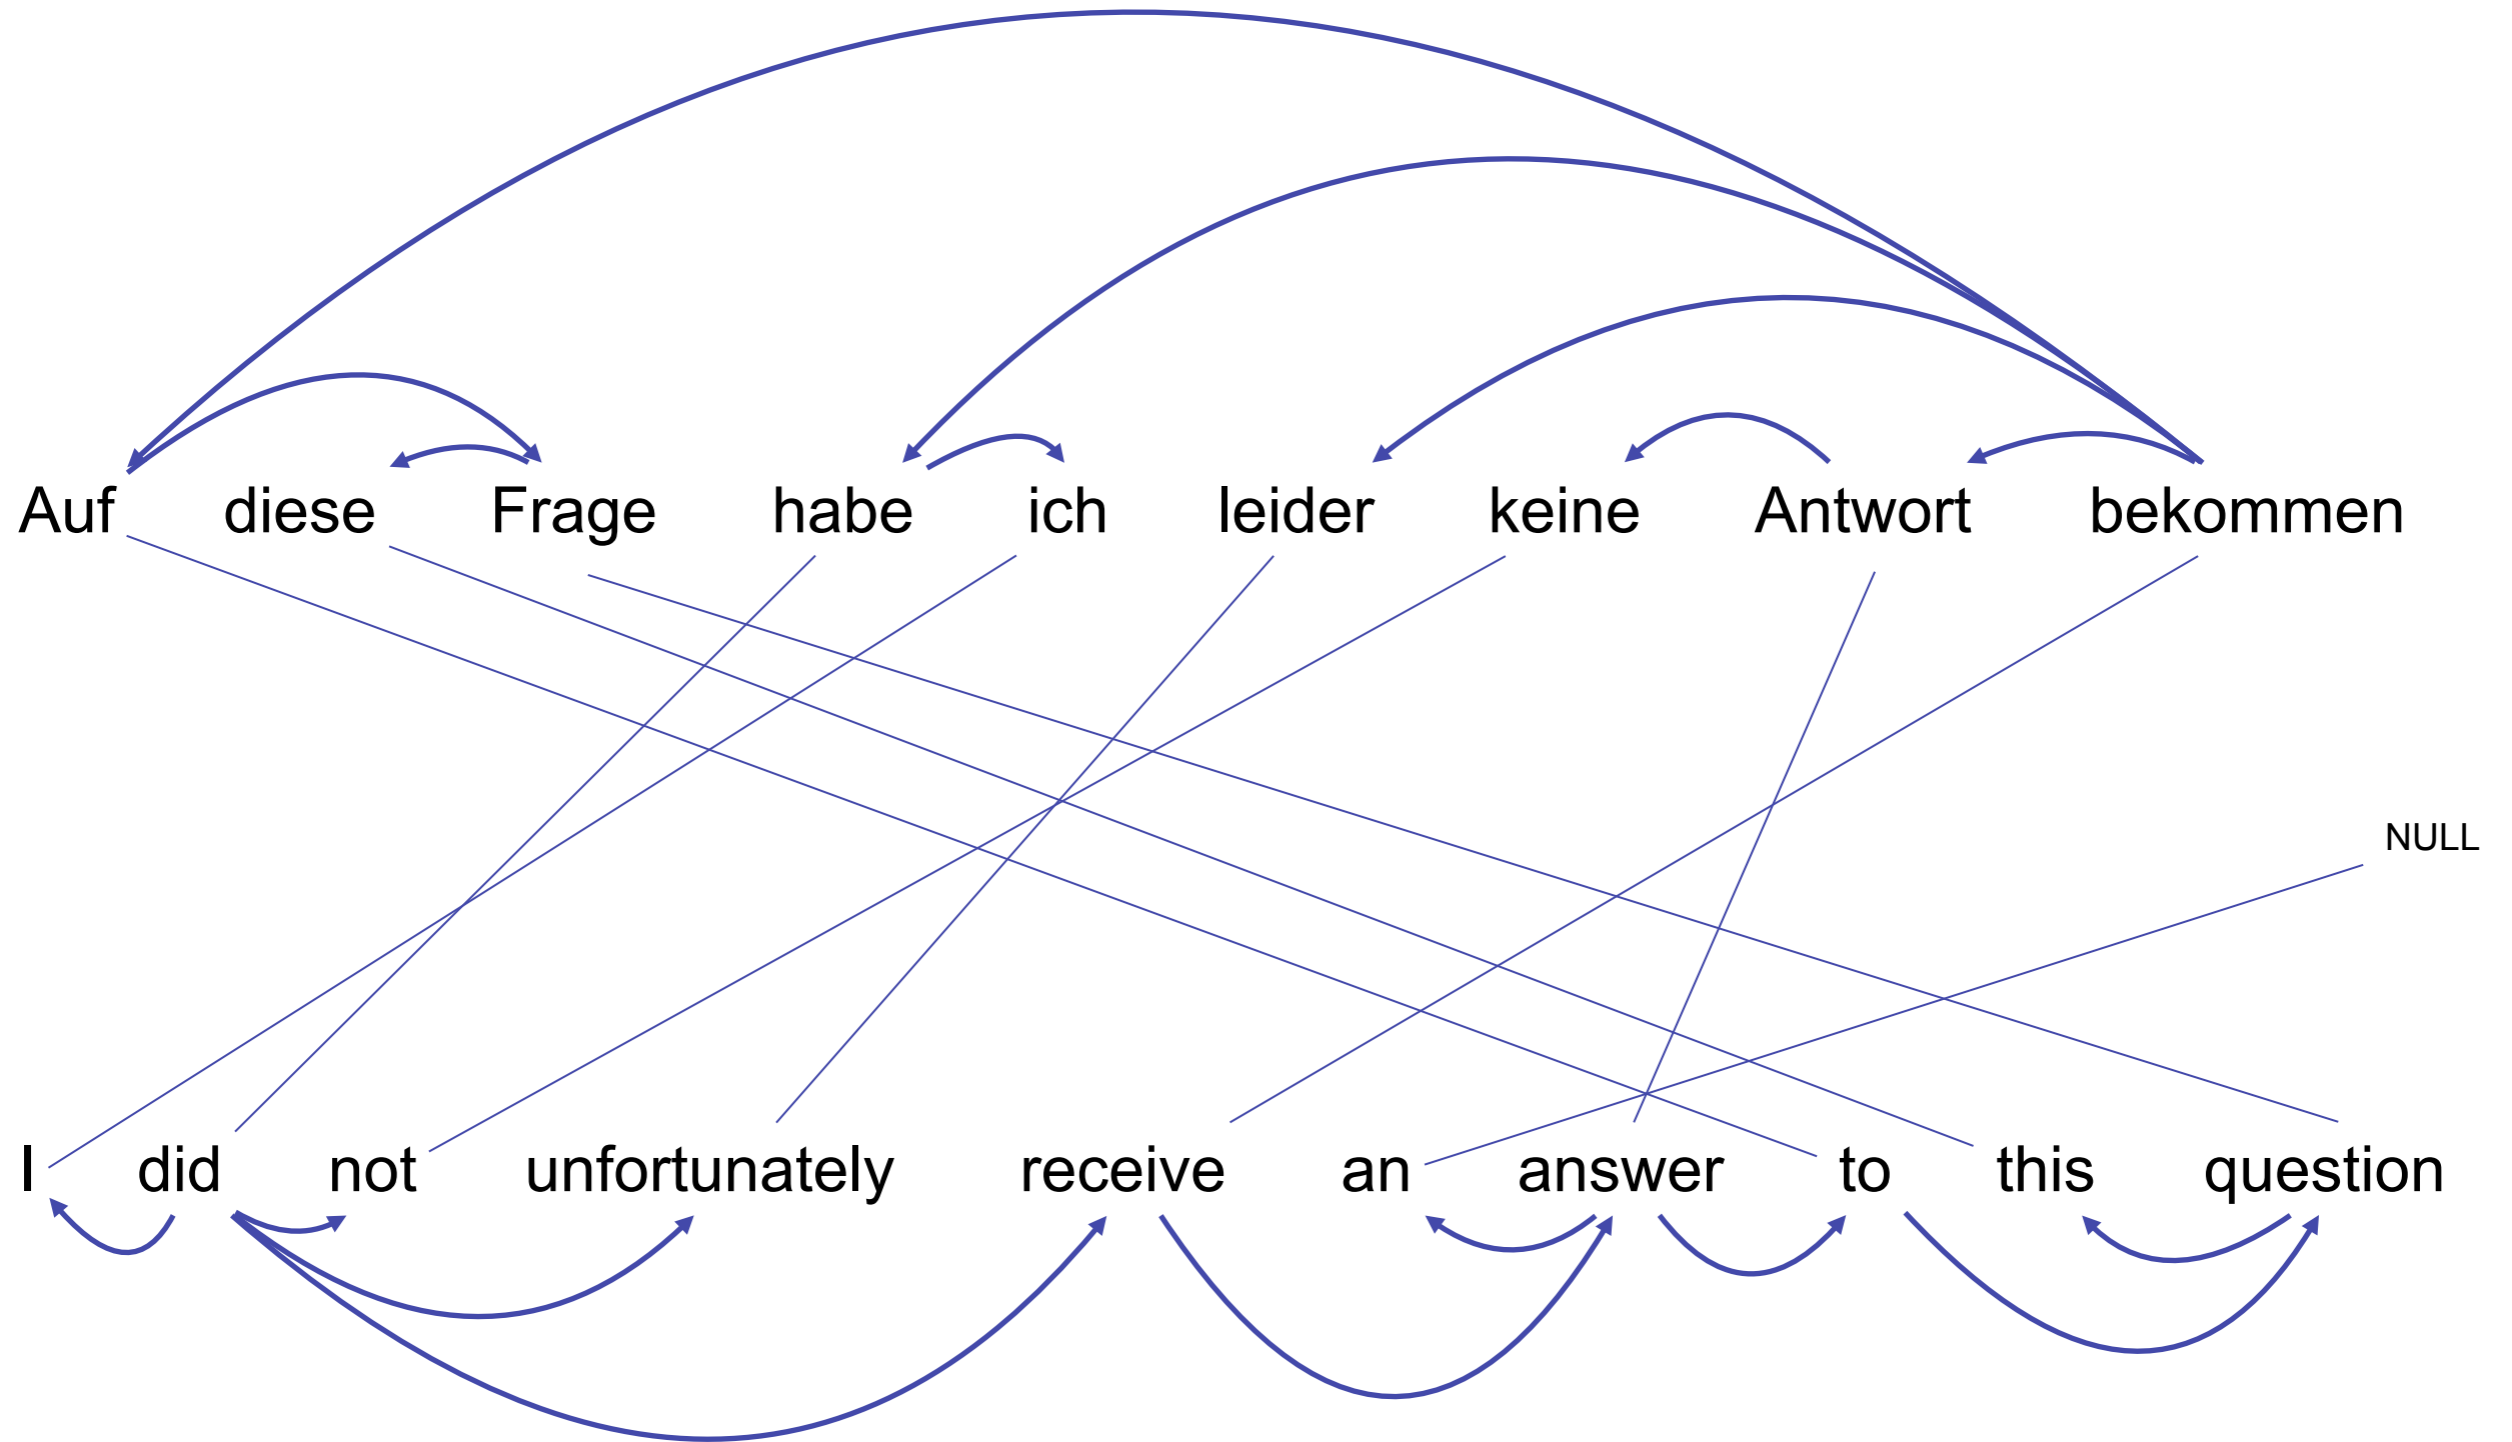

*Parse trees with deeper structure have also been used.*

# Single-Tree Translation Models

- Either source or target has a hidden tree/parse structure
  - Also known as “tree-to-string” or “tree-transducer” models
- The side with the tree generates words/phrases in tree, not string, order.
- Nodes in the tree also generate words/phrases on the other side.
- English side is often parsed, whether it's source or target, since English parsing is more advanced.

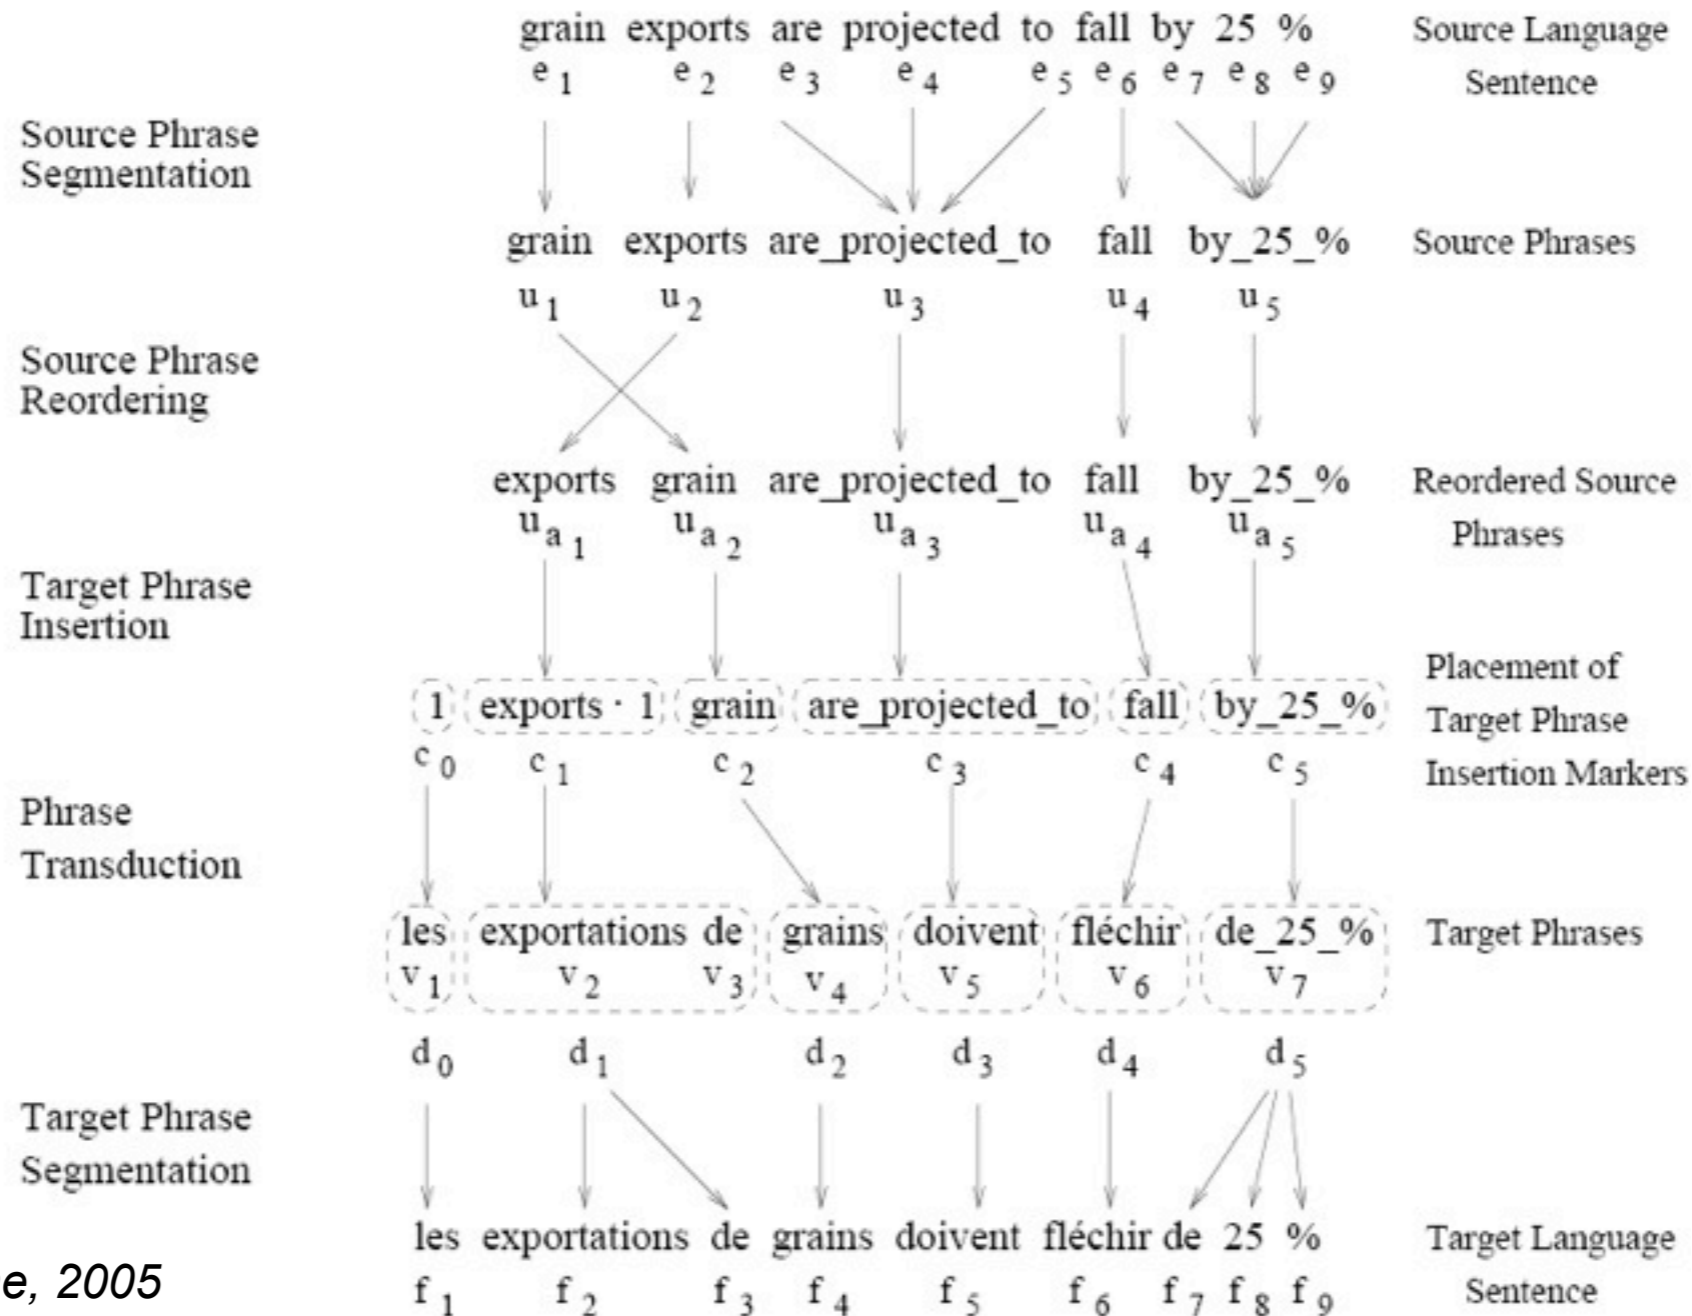

# Tree-Tree Translation Models

# Tree-Tree Translation Models

- Both sides have hidden tree structure
  - Can be represented with a “synchronous” grammar
- Some models assume isomorphic trees, where parent-child relations are preserved; others do not.
- Trees can be fixed in advance by monolingual parsers or induced from data (e.g. Hiero).
- Cheap trees: project from one side to the other

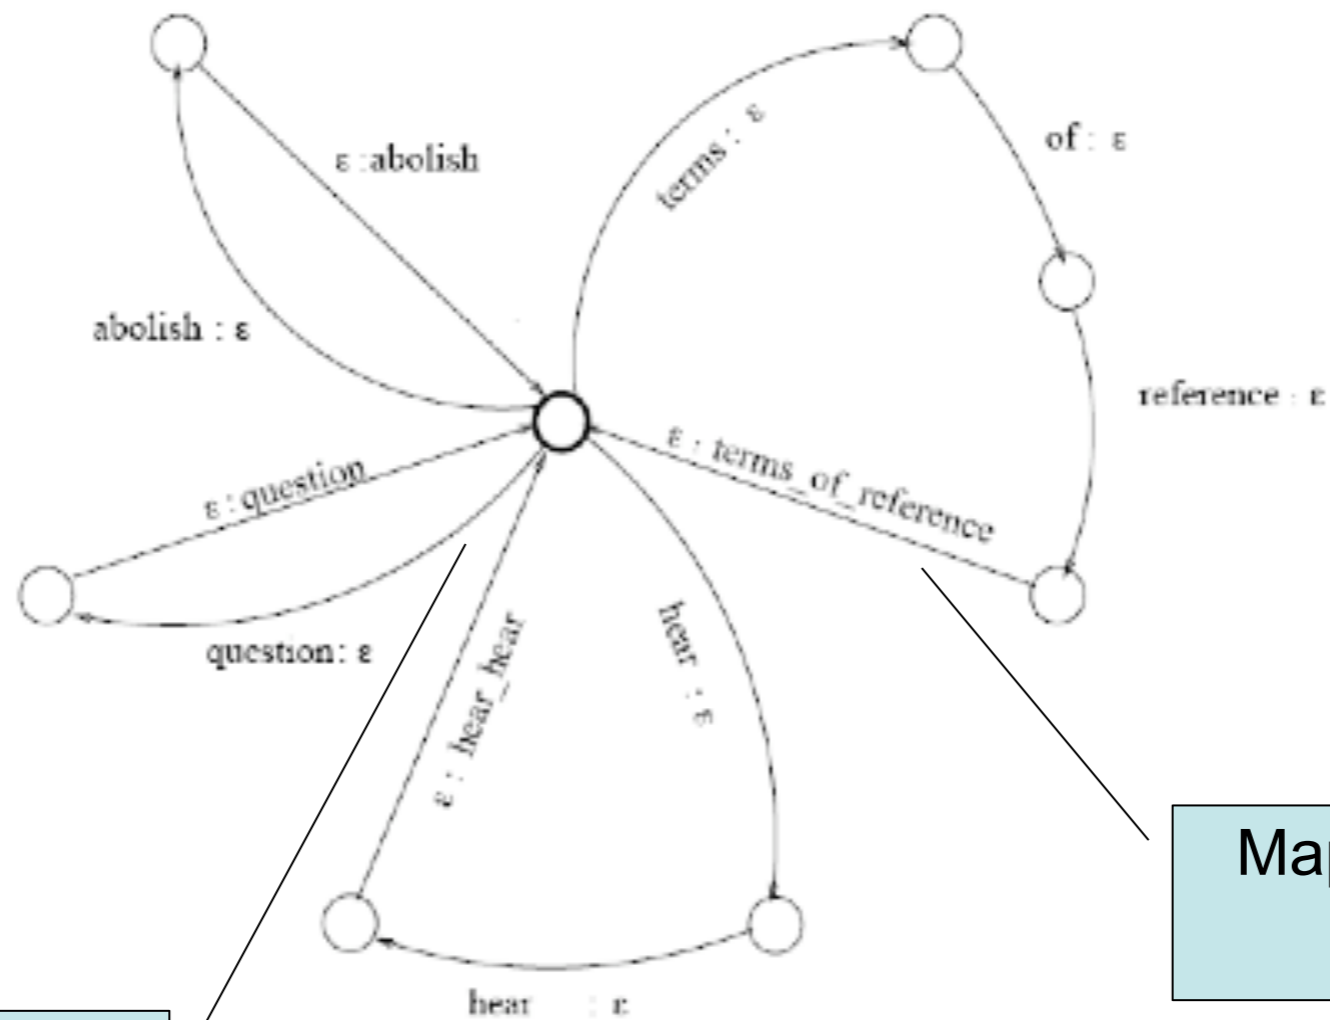

# Finite State Models

Kumar, Deng & Byrne, 2005

# Finite State Models

*First transducer in the pipeline*

Here a unigram model of phrases

Map distinct words to phrases

*Kumar, Deng & Byrne, 2005*

# Finite State Models

- Natural composition with other finite state processes, e.g. Chinese word segmentation
- Standard algorithms and widely available tools (e.g. AT&T fsm toolkit)
- Limit reordering to finite offset
- Often impractical to compose all finite state machines offline

# Case Study: Inversion Transduction Grammar

# Syntactically-Motivated Distortion

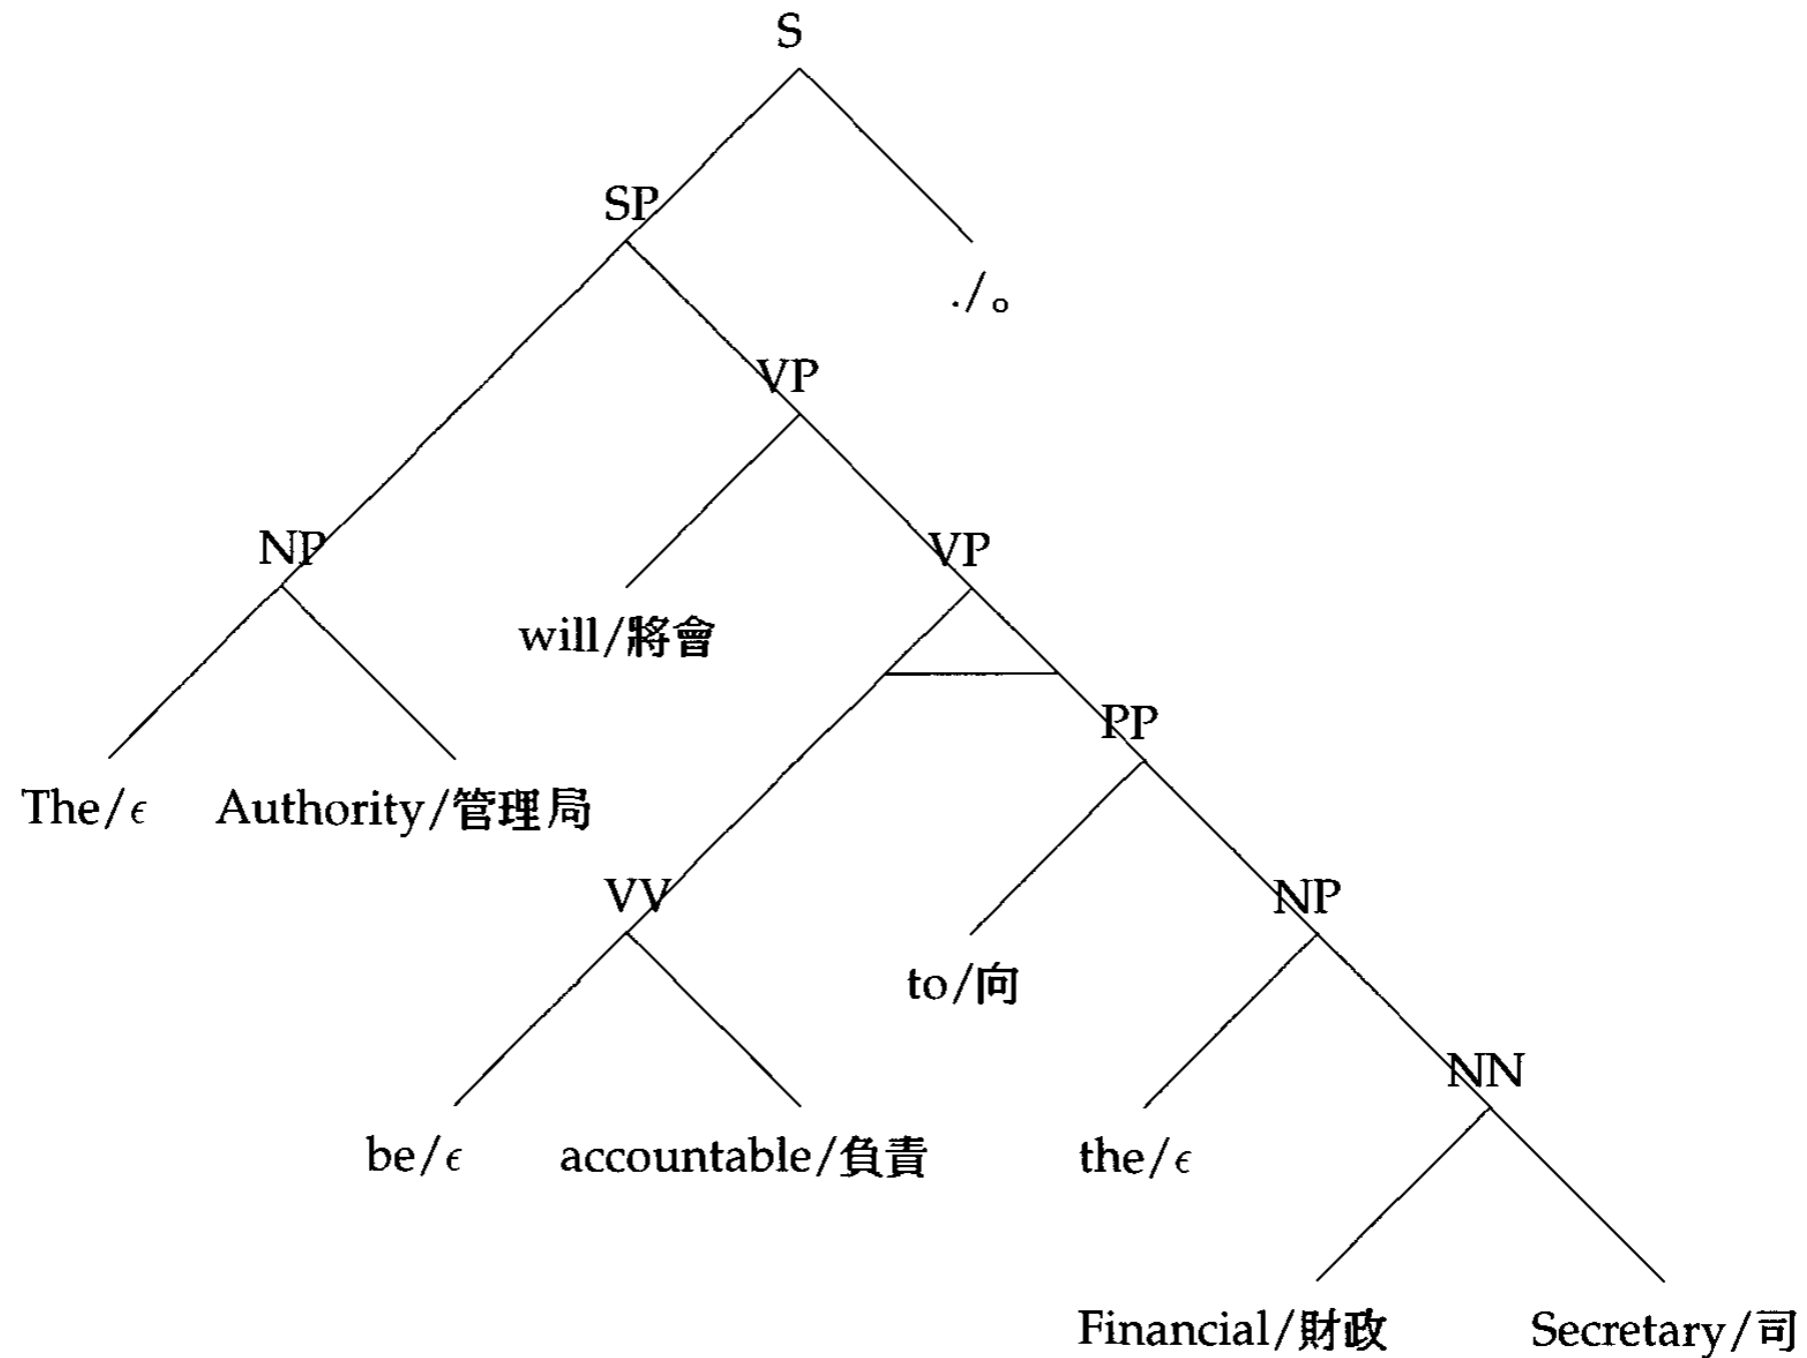

The Authority will be accountable to the Financial Secretary.

管理局將會向財政司負責。

*(Authority will to Financial Secretary accountable.)*

# Syntactically-Motivated Distortion

# ITG Overview

- Special case of synchronous CFG
- One, joint nonterminal per bilingual node
- Children are translated monotonically, or reversed
- Binarized normal form
- Mostly used for exact, polytime alignment

# ITG Rules

# Learning Word Translations from Parallel Text

The “IBM Models”

# Lexical translation

- How to translate a word → look up in dictionary

**Haus** — *house, building, home, household, shell.*

- *Multiple translations*

- some more frequent than others
- for instance: *house*, and *building* most common
- special cases: *Haus* of a *snail* is its *shell*

- Note: During all the lectures, we will translate from a foreign language into English

# Collect statistics

- Look at a *parallel corpus* (German text along with English translation)

<b>Translation of <i>Haus</i></b>	<b>Count</b>
<i>house</i>	8,000
<i>building</i>	1,600
<i>home</i>	200
<i>household</i>	150
<i>shell</i>	50

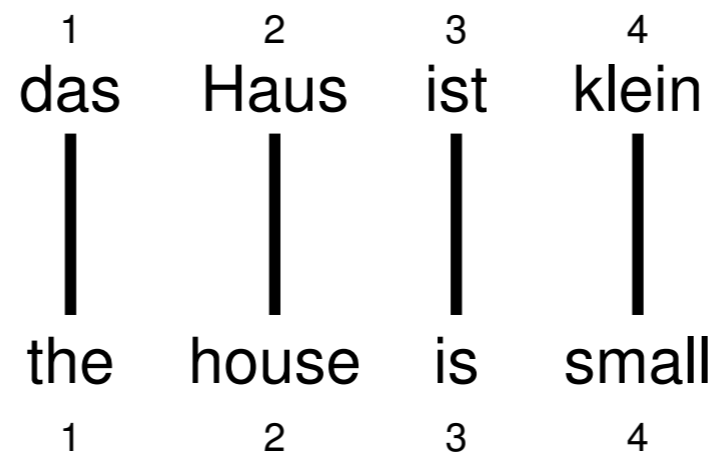

## Estimate translation probabilities

- *Maximum likelihood estimation*

$$p_f(e) = \begin{cases} 0.8 & \text{if } e = \textit{house}, \\ 0.16 & \text{if } e = \textit{building}, \\ 0.02 & \text{if } e = \textit{home}, \\ 0.015 & \text{if } e = \textit{household}, \\ 0.005 & \text{if } e = \textit{shell}. \end{cases}$$

## Alignment

- In a parallel text (or when we translate), we **align** words in one language with the words in the other

- Word *positions* are numbered 1–4

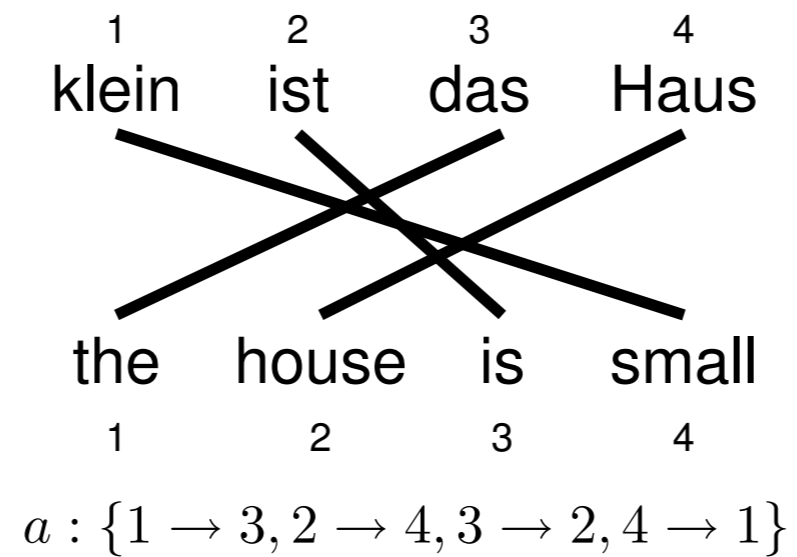

## Alignment function

- Formalizing *alignment* with an **alignment function**
- Mapping an English target word at position  $i$  to a German source word at position  $j$  with a function  $a : i \rightarrow j$
- Example

$$a : \{1 \rightarrow 1, 2 \rightarrow 2, 3 \rightarrow 3, 4 \rightarrow 4\}$$

## Reordering

- Words may be **reordered** during translation

## One-to-many translation

- A source word may translate into **multiple** target words

## Dropping words

- Words may be **dropped** when translated
  - The German article *das* is dropped

## Inserting words

- Words may be **added** during translation
  - The English *just* does not have an equivalent in German
  - We still need to map it to something: special NULL token

$$a : \{1 \rightarrow 1, 2 \rightarrow 2, 3 \rightarrow 3, 4 \rightarrow 0, 5 \rightarrow 4\}$$

## IBM Model 1

- *Generative model*: break up translation process into smaller steps
  - **IBM Model 1** only uses *lexical translation*
- Translation probability
  - for a foreign sentence  $\mathbf{f} = (f_1, \dots, f_{l_f})$  of length  $l_f$
  - to an English sentence  $\mathbf{e} = (e_1, \dots, e_{l_e})$  of length  $l_e$
  - with an alignment of each English word  $e_j$  to a foreign word  $f_i$  according to the alignment function  $a : j \rightarrow i$

$$p(\mathbf{e}, a | \mathbf{f}) = \frac{\epsilon}{(l_f + 1)^{l_e}} \prod_{j=1}^{l_e} t(e_j | f_{a(j)})$$

- parameter  $\epsilon$  is a *normalization constant*

## Example

<i>das</i>		<i>Haus</i>		<i>ist</i>		<i>klein</i>	
<i>e</i>	$t(e f)$	<i>e</i>	$t(e f)$	<i>e</i>	$t(e f)$	<i>e</i>	$t(e f)$
<i>the</i>	0.7	<i>house</i>	0.8	<i>is</i>	0.8	<i>small</i>	0.4
<i>that</i>	0.15	<i>building</i>	0.16	<i>'s</i>	0.16	<i>little</i>	0.4
<i>which</i>	0.075	<i>home</i>	0.02	<i>exists</i>	0.02	<i>short</i>	0.1
<i>who</i>	0.05	<i>household</i>	0.015	<i>has</i>	0.015	<i>minor</i>	0.06
<i>this</i>	0.025	<i>shell</i>	0.005	<i>are</i>	0.005	<i>petty</i>	0.04

$$\begin{aligned} p(e, a|f) &= \frac{\epsilon}{4^3} \times t(\text{the}|\text{das}) \times t(\text{house}|\text{Haus}) \times t(\text{is}|\text{ist}) \times t(\text{small}|\text{klein}) \\ &= \frac{\epsilon}{4^3} \times 0.7 \times 0.8 \times 0.8 \times 0.4 \\ &= 0.0028\epsilon \end{aligned}$$

## Learning lexical translation models

- We would like to *estimate* the lexical translation probabilities  $t(e|f)$  from a parallel corpus
- ... but we do not have the alignments
- **Chicken and egg problem**
  - if we had the *alignments*,
    - we could estimate the *parameters* of our generative model
  - if we had the *parameters*,
    - we could estimate the *alignments*

## EM algorithm

- **Incomplete data**
  - if we had *complete data*, would could estimate *model*
  - if we had *model*, we could fill in the *gaps in the data*
- **Expectation Maximization (EM)** in a nutshell
  - initialize model parameters (e.g. uniform)
  - assign probabilities to the missing data
  - estimate model parameters from completed data
  - iterate

## EM algorithm

- Initial step: all alignments equally likely
- Model learns that, e.g., *la* is often aligned with *the*

## EM algorithm

- After one iteration
- Alignments, e.g., between *la* and *the* are more likely

## EM algorithm

- After another iteration
- It becomes apparent that alignments, e.g., between *fleur* and *flower* are more likely (**pigeon hole principle**)

## EM algorithm

... la maison ... la maison bleu ... la fleur ...  
/ | | X | |  
... the house ... the blue house ... the flower ...

- Convergence
- Inherent hidden structure revealed by EM

## EM algorithm

... la maison ... la maison bleu ... la fleur ...  
 / | | | X | |  
 ... the house ... the blue house ... the flower ...

$p(\text{la}|\text{the}) = 0.453$   
 $p(\text{le}|\text{the}) = 0.334$   
 $p(\text{maison}|\text{house}) = 0.876$   
 $p(\text{bleu}|\text{blue}) = 0.563$   
 ...

- Parameter estimation from the aligned corpus

## IBM Model 1 and EM

- EM Algorithm consists of two steps
- **Expectation-Step**: Apply model to the data
  - parts of the model are hidden (here: alignments)
  - using the model, assign probabilities to possible values
- **Maximization-Step**: Estimate model from data
  - take assign values as fact
  - collect counts (weighted by probabilities)
  - estimate model from counts
- Iterate these steps until **convergence**

## IBM Model 1 and EM

- We need to be able to compute:
  - Expectation-Step: probability of alignments
  - Maximization-Step: count collection

## IBM Model 1 and EM

- **Probabilities**

$$\begin{aligned}
 p(\text{the}|\text{la}) &= 0.7 & p(\text{house}|\text{la}) &= 0.05 \\
 p(\text{the}|\text{maison}) &= 0.1 & p(\text{house}|\text{maison}) &= 0.8
 \end{aligned}$$

- **Alignments**

## IBM Model 1 and EM

- **Probabilities**

$$\begin{aligned}
 p(\text{the}|\text{la}) &= 0.7 & p(\text{house}|\text{la}) &= 0.05 \\
 p(\text{the}|\text{maison}) &= 0.1 & p(\text{house}|\text{maison}) &= 0.8
 \end{aligned}$$

- **Alignments**

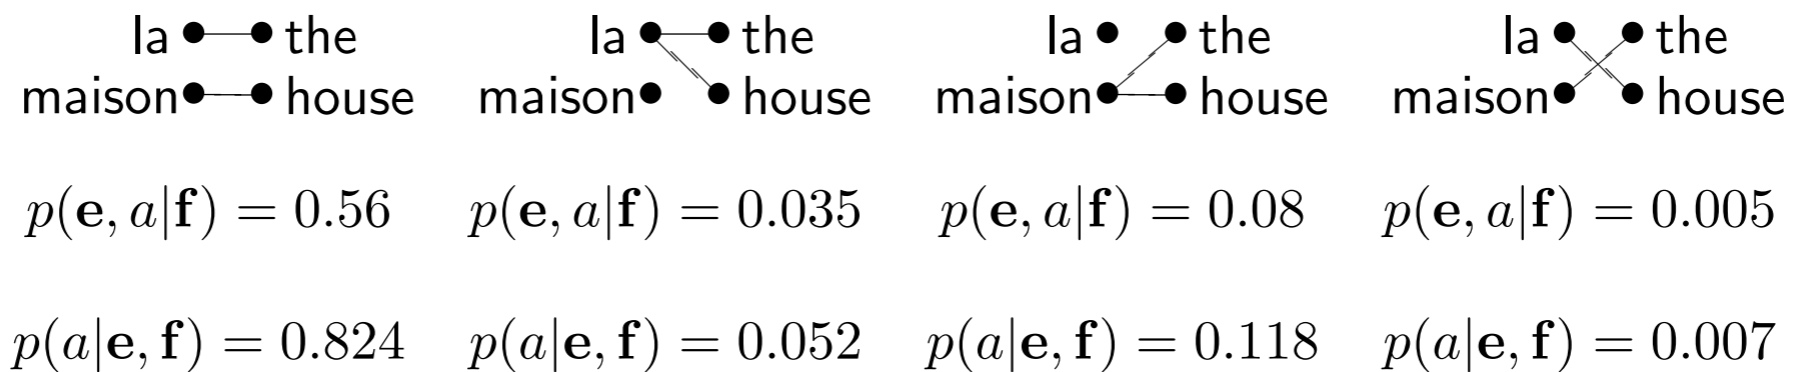

## IBM Model 1 and EM

- Probabilities

$$\begin{aligned}
 p(\text{the}|\text{la}) &= 0.7 & p(\text{house}|\text{la}) &= 0.05 \\
 p(\text{the}|\text{maison}) &= 0.1 & p(\text{house}|\text{maison}) &= 0.8
 \end{aligned}$$

- Alignments

- Counts

$$\begin{aligned}
 c(\text{the}|\text{la}) &= 0.824 + 0.052 & c(\text{house}|\text{la}) &= 0.052 + 0.007 \\
 c(\text{the}|\text{maison}) &= 0.118 + 0.007 & c(\text{house}|\text{maison}) &= 0.824 + 0.118
 \end{aligned}$$

## IBM Model 1 and EM: Expectation Step

- We need to compute  $p(a|\mathbf{e}, \mathbf{f})$
- Applying the *chain rule*:

$$p(a|\mathbf{e}, \mathbf{f}) = \frac{p(\mathbf{e}, a|\mathbf{f})}{p(\mathbf{e}|\mathbf{f})}$$

- We already have the formula for  $p(\mathbf{e}, \mathbf{a}|\mathbf{f})$  (definition of Model 1)

## IBM Model 1 and EM: Expectation Step

- We need to compute  $p(\mathbf{e}|\mathbf{f})$

$$\begin{aligned} p(\mathbf{e}|\mathbf{f}) &= \sum_a p(\mathbf{e}, a|\mathbf{f}) \\ &= \sum_{a(1)=0}^{l_f} \dots \sum_{a(l_e)=0}^{l_f} p(\mathbf{e}, a|\mathbf{f}) \\ &= \sum_{a(1)=0}^{l_f} \dots \sum_{a(l_e)=0}^{l_f} \frac{\epsilon}{(l_f + 1)^{l_e}} \prod_{j=1}^{l_e} t(e_j|f_{a(j)}) \end{aligned}$$

## IBM Model 1 and EM: Expectation Step

$$\begin{aligned} p(\mathbf{e}|\mathbf{f}) &= \sum_{a(1)=0}^{l_f} \dots \sum_{a(l_e)=0}^{l_f} \frac{\epsilon}{(l_f + 1)^{l_e}} \prod_{j=1}^{l_e} t(e_j|f_{a(j)}) \\ &= \frac{\epsilon}{(l_f + 1)^{l_e}} \sum_{a(1)=0}^{l_f} \dots \sum_{a(l_e)=0}^{l_f} \prod_{j=1}^{l_e} t(e_j|f_{a(j)}) \\ &= \frac{\epsilon}{(l_f + 1)^{l_e}} \prod_{j=1}^{l_e} \sum_{i=0}^{l_f} t(e_j|f_i) \end{aligned}$$

- Note the trick in the last line
  - removes the need for an *exponential* number of products
  - this makes IBM Model 1 estimation **tractable**

## IBM Model 1 and EM: Expectation Step

- Combine what we have:

$$\begin{aligned} p(\mathbf{a}|\mathbf{e}, \mathbf{f}) &= p(\mathbf{e}, \mathbf{a}|\mathbf{f})/p(\mathbf{e}|\mathbf{f}) \\ &= \frac{\frac{\epsilon}{(l_f+1)^{l_e}} \prod_{j=1}^{l_e} t(e_j|f_{a(j)})}{\frac{\epsilon}{(l_f+1)^{l_e}} \prod_{j=1}^{l_e} \sum_{i=0}^{l_f} t(e_j|f_i)} \\ &= \prod_{j=1}^{l_e} \frac{t(e_j|f_{a(j)})}{\sum_{i=0}^{l_f} t(e_j|f_i)} \end{aligned}$$

## IBM Model 1 and EM: Maximization Step

- Now we have to *collect counts*
- Evidence from a sentence pair  $\mathbf{e}, \mathbf{f}$  that word  $e$  is a translation of word  $f$ :

$$c(e|f; \mathbf{e}, \mathbf{f}) = \sum_a p(a|\mathbf{e}, \mathbf{f}) \sum_{j=1}^{l_e} \delta(e, e_j) \delta(f, f_{a(j)})$$

- With the same simplification as before:

$$c(e|f; \mathbf{e}, \mathbf{f}) = \frac{t(e|f)}{\sum_{j=1}^{l_e} t(e|f_{a(j)})} \sum_{j=1}^{l_e} \delta(e, e_j) \sum_{i=0}^{l_f} \delta(f, f_i)$$

## IBM Model 1 and EM: Maximization Step

- After collecting these counts over a corpus, we can estimate the model:

$$t(e|f; \mathbf{e}, \mathbf{f}) = \frac{\sum_{(\mathbf{e}, \mathbf{f})} c(e|f; \mathbf{e}, \mathbf{f})}{\sum_f \sum_{(\mathbf{e}, \mathbf{f})} c(e|f; \mathbf{e}, \mathbf{f})}$$

## IBM Model 1 and EM: Pseudocode

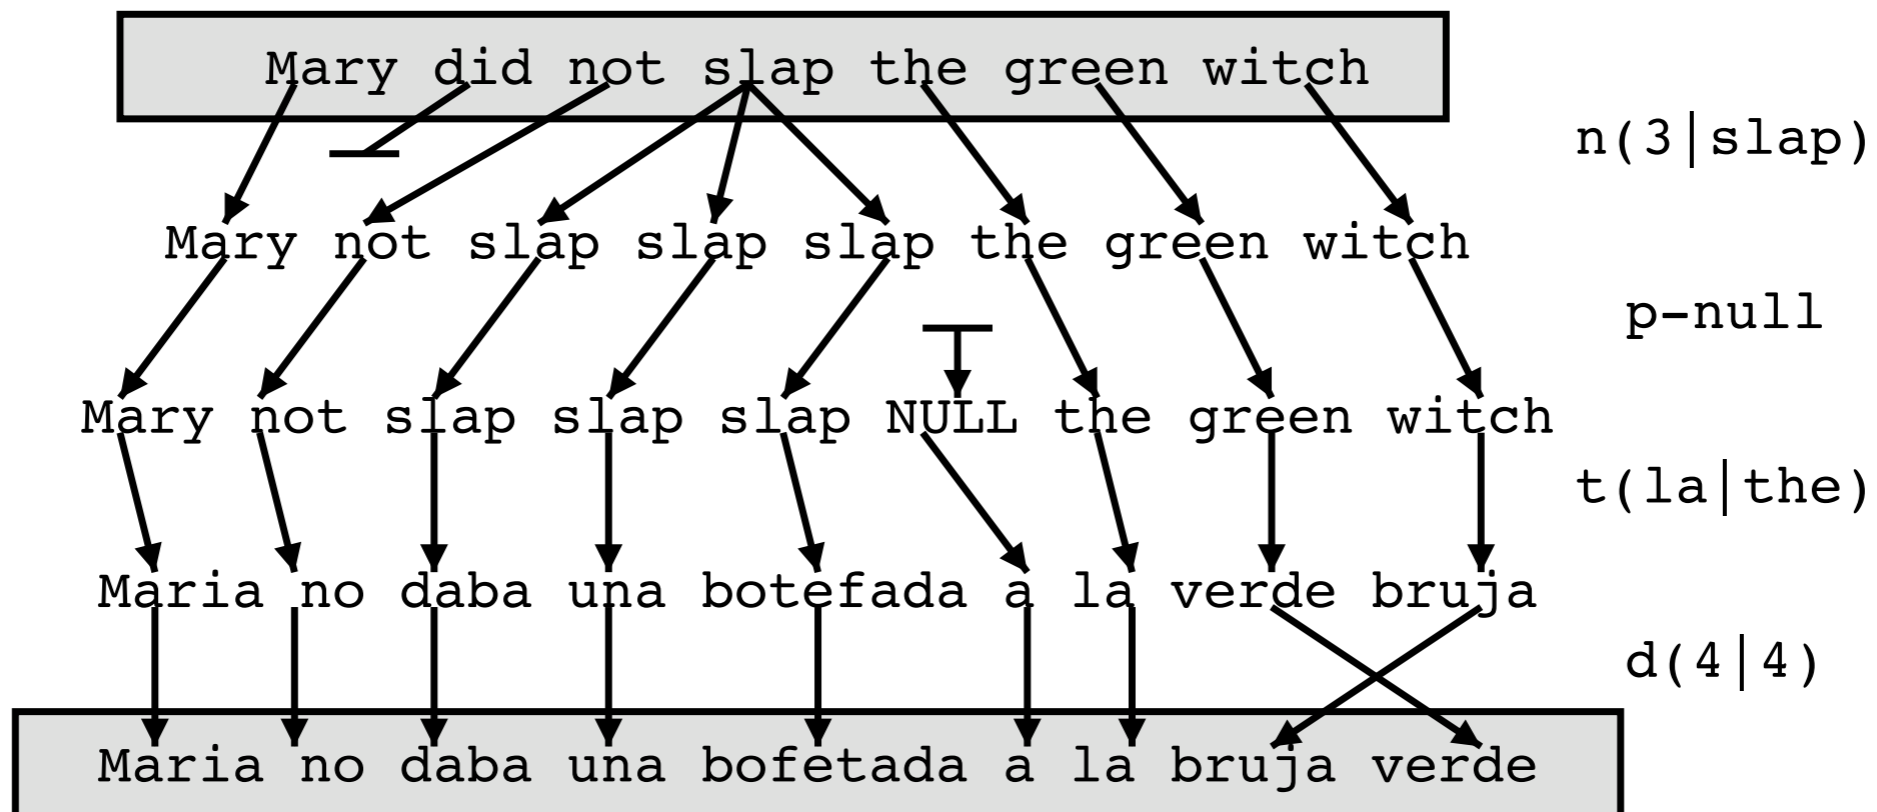

```
initialize  $t(e|f)$  uniformly
do
  set count( $e|f$ ) to 0 for all  $e, f$ 
  set total( $f$ ) to 0 for all  $f$ 
  for all sentence pairs ( $e_s, f_s$ )
    for all words  $e$  in  $e_s$ 
      total_s = 0
      for all words  $f$  in  $f_s$ 
        total_s +=  $t(e|f)$ 
    for all words  $e$  in  $e_s$ 
      for all words  $f$  in  $f_s$ 
        count( $e|f$ ) +=  $t(e|f) / \text{total}_s$ 
        total( $f$ ) +=  $t(e|f) / \text{total}_s$ 
  for all  $f$  in domain( total(.) )
    for all  $e$  in domain( count(.|f) )
       $t(e|f) = \text{count}(e|f) / \text{total}(f)$ 
until convergence
```

## Higher IBM Models

IBM Model 1	lexical translation
IBM Model 2	adds absolute <b>reordering model</b>
IBM Model 3	adds <b>fertility model</b>
IBM Model 4	relative reordering model
IBM Model 5	fixes <b>deficiency</b>

- Only IBM Model 1 has *global maximum*
  - training of a higher IBM model builds on previous model
- Computationally biggest change in Model 3
  - trick to simplify estimation does not work anymore
  - *exhaustive* count collection becomes computationally too expensive
  - **sampling** over high probability alignments is used instead

# IBM Model 4

# Word alignment

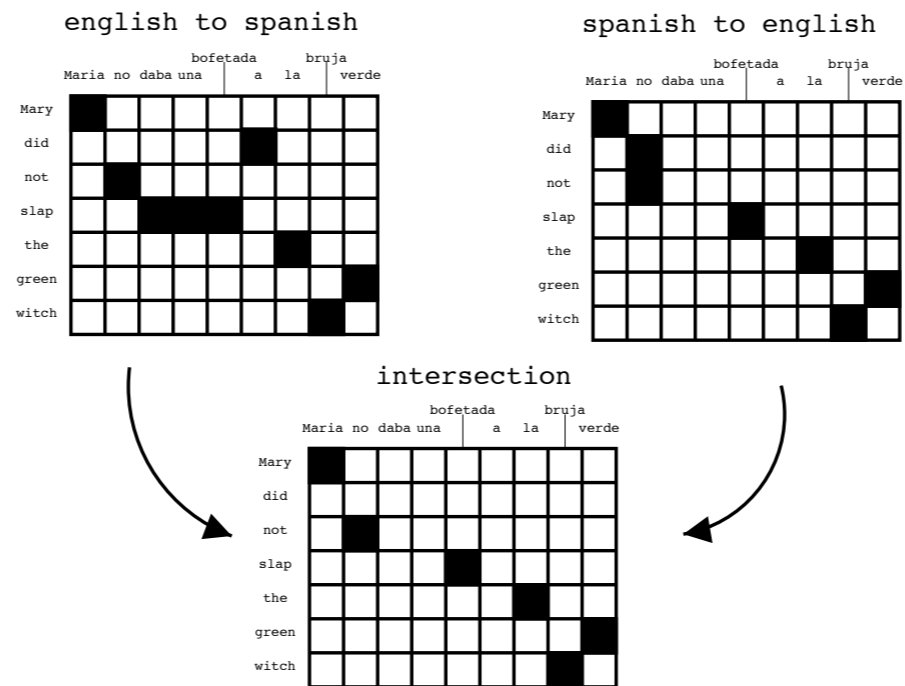

- Notion of **word alignment** valuable
- Shared task at NAACL 2003 and ACL 2005 workshops

				bofetada		bruja		
	Maria	no	daba	una	a	la	verde	
Mary	■

green							■	
witch							■	

## Word alignment with IBM models

- IBM Models create a *many-to-one* mapping
  - words are aligned using an **alignment function**
  - a function may return the same value for different input (one-to-many mapping)
  - a function can not return multiple values for one input (*no many-to-one* mapping)
- But we need *many-to-many* mappings

# Symmetrizing word alignments

- *Intersection* of GIZA++ bidirectional alignments

## Symmetrizing word alignments

- *Grow* additional alignment points [Och and Ney, CompLing2003]

## Growing heuristic

```
GROW-DIAG-FINAL(e2f, f2e):  
  neighboring = ((-1,0), (0,-1), (1,0), (0,1), (-1,-1), (-1,1), (1,-1), (1,1))  
  alignment = intersect(e2f, f2e);  
  GROW-DIAG(); FINAL(e2f); FINAL(f2e);
```

```
GROW-DIAG():  
  iterate until no new points added  
  for english word e = 0 ... en  
    for foreign word f = 0 ... fn  
      if ( e aligned with f )  
        for each neighboring point ( e-new, f-new ):

        add alignment point ( e-new, f-new )
```

# Specialized Translation Models: Named Entities

## Translating Words in a Sentence

- Models will automatically learn entries in probabilistic translation dictionaries, for instance  $p(\text{elle}|\text{she})$ , from co-occurrences in aligned sentences of a parallel text.

- For some kinds of words/phrases, this is less effective. For example:

numbers

dates

named entities (NE)

The reason: these constitute a large open class of words that will not all occur even in the largest bitext. Plus, there are regularities in translation of numbers/dates/NE.

## Handling Named Entities

- For many language pairs, and particularly those which do not share an alphabet, transliteration of person and place names is the desired method of translation.
- General Method:
  1. Identify NE's via classifier
  2. Transliterate name
  3. Translate/reorder honorifics
- Also useful for alignment. Consider the case of Inuktitut-English alignment, where Inuktitut renderings of European names are highly nondeterministic.

# Transliteration

Inuktitut rendering of  
English names **changes** the  
string **significantly** but **not**  
**deterministically**

## Useful Types of Word Analysis

- Number/Date Handling
- Named Entity Tagging/Transliteration
- Morphological Analysis
  - Analyze a word to its root form  
(at least for word alignment)  
was -> is                      believing -> believe  
rumineraï -> ruminer      ruminiez -> ruminer
  - As a dimensionality reduction technique
  - To allow lookup in existing dictionary

# Learning Word Translation Dictionaries Using Minimal Resources

# Learning Translation Lexicons for Low-Resource Languages

{Serbian Uzbek Romanian Bengali}

—English

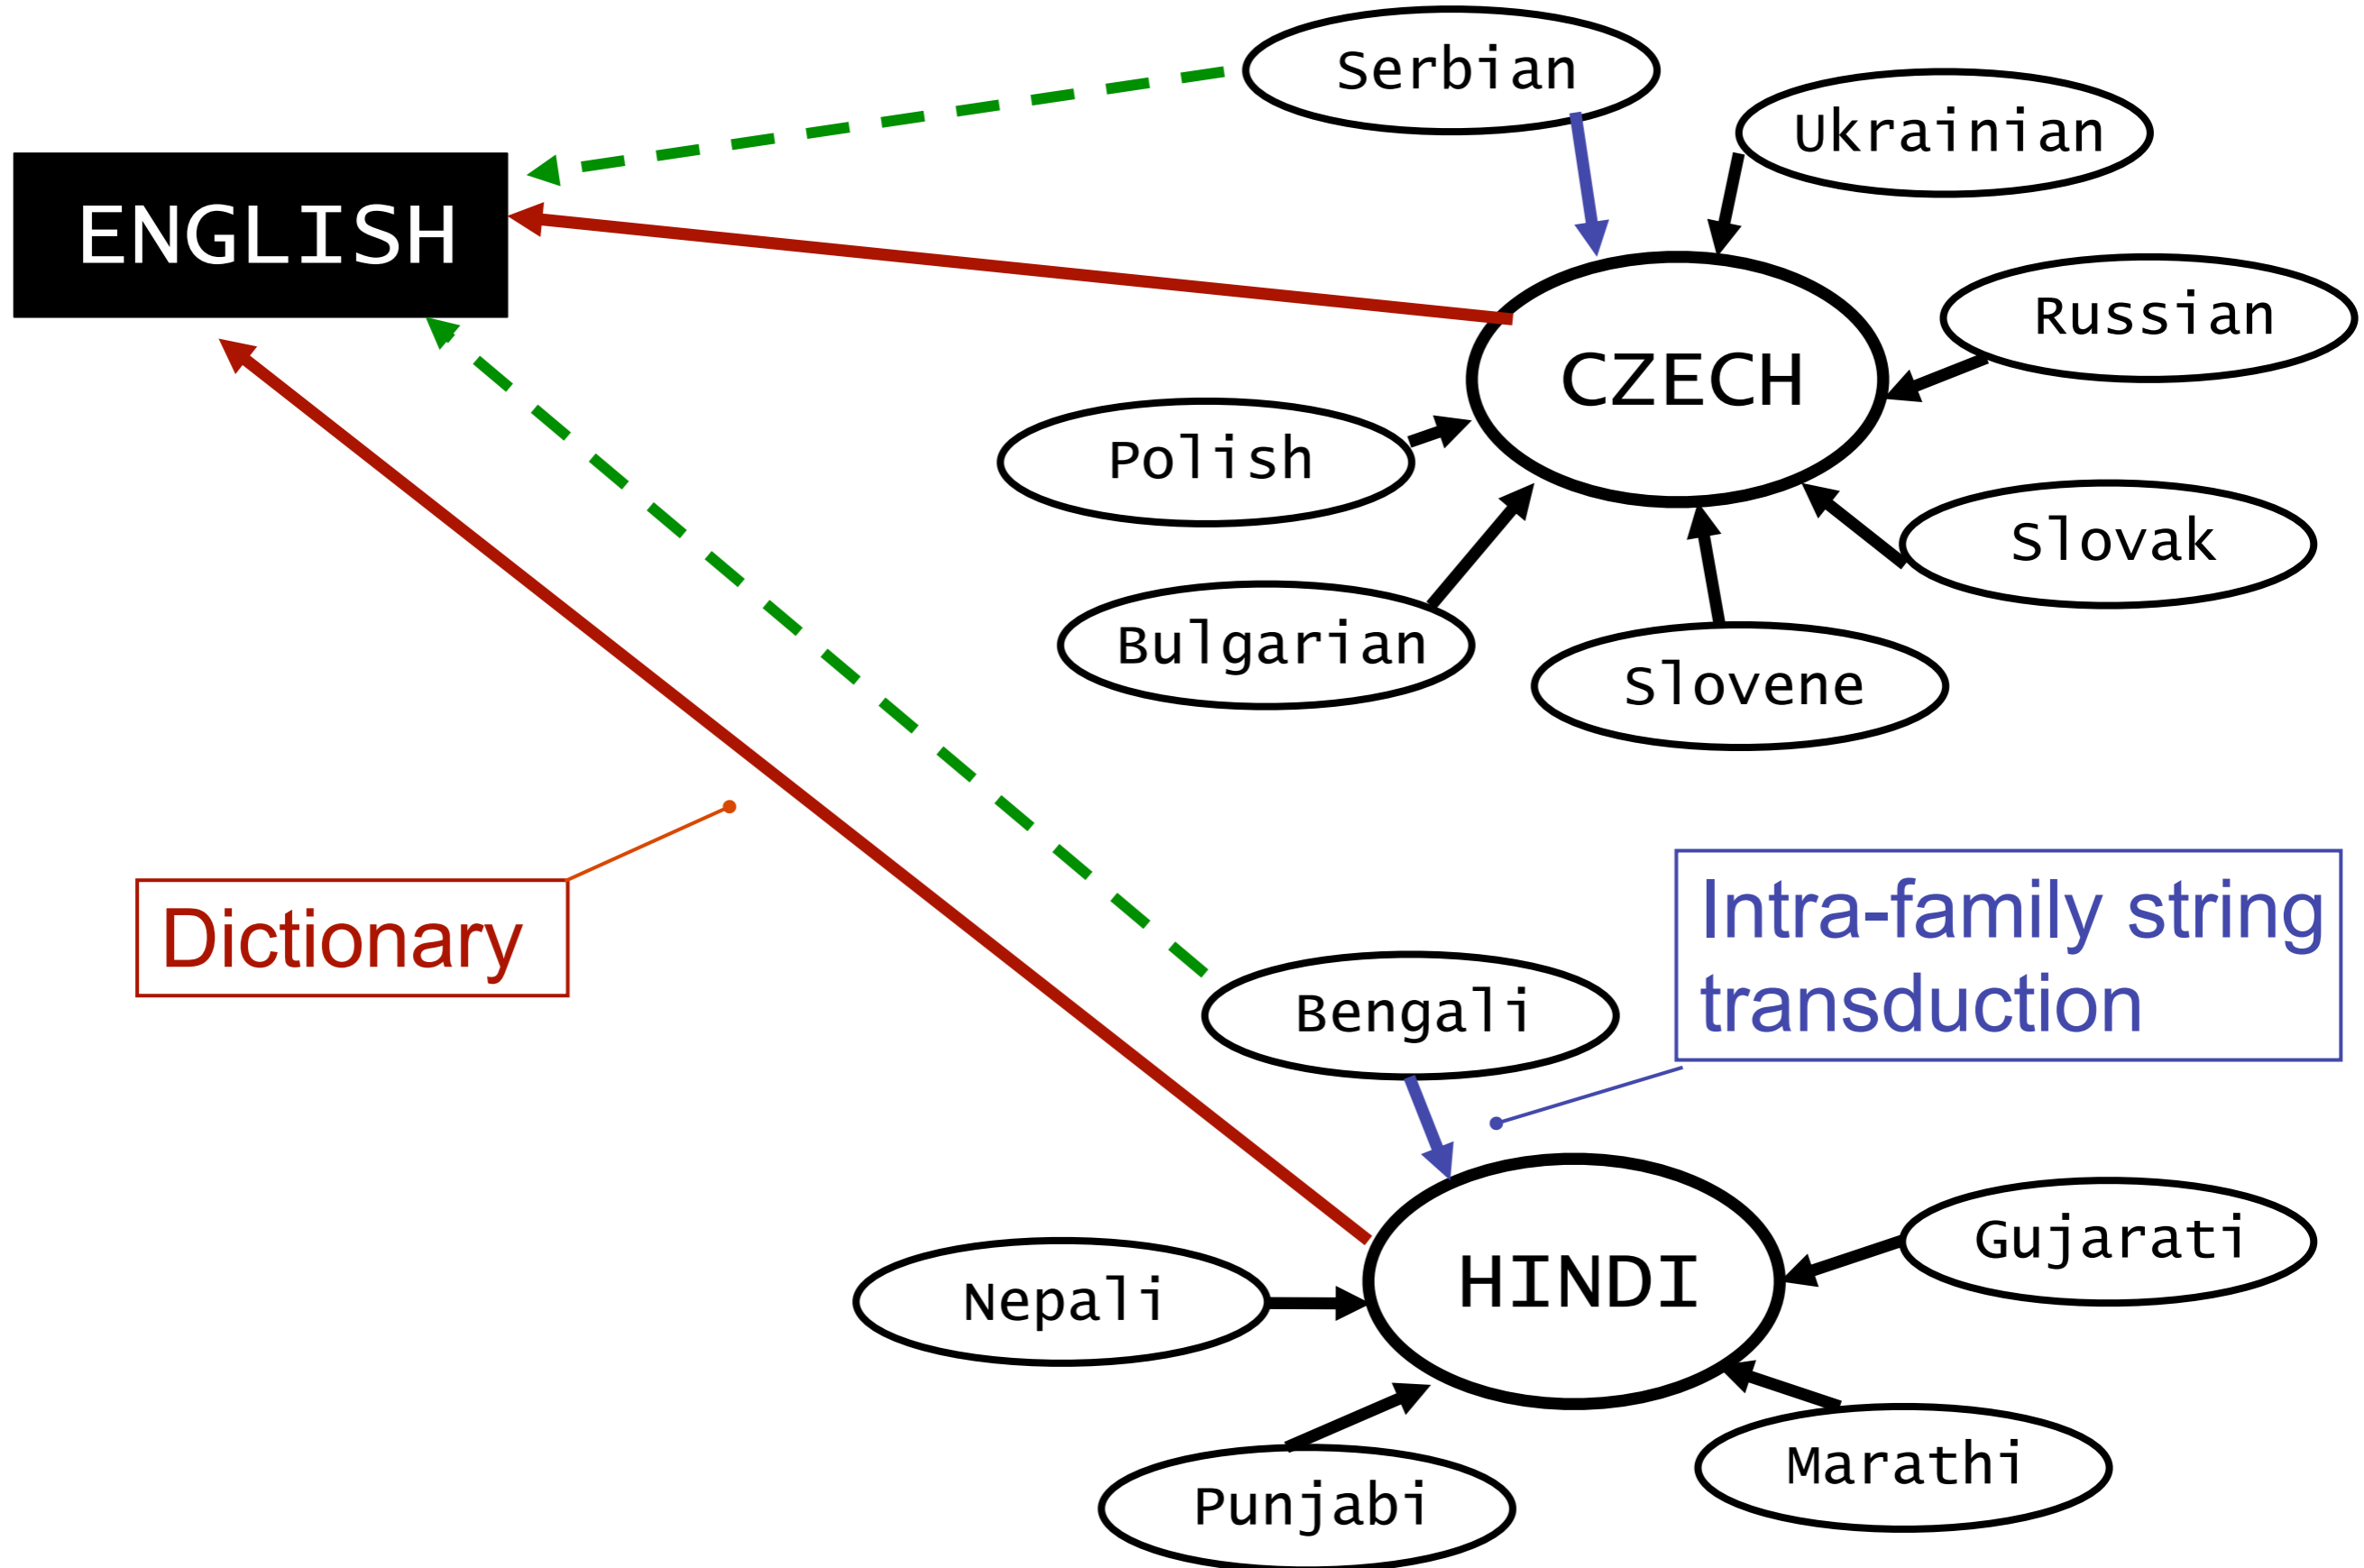

Problem: Scarce resources . . .

- Large parallel texts are very helpful, but often unavailable
- Often, no “seed” translation lexicon is available
- Neither are resources such as parsers, taggers, thesauri

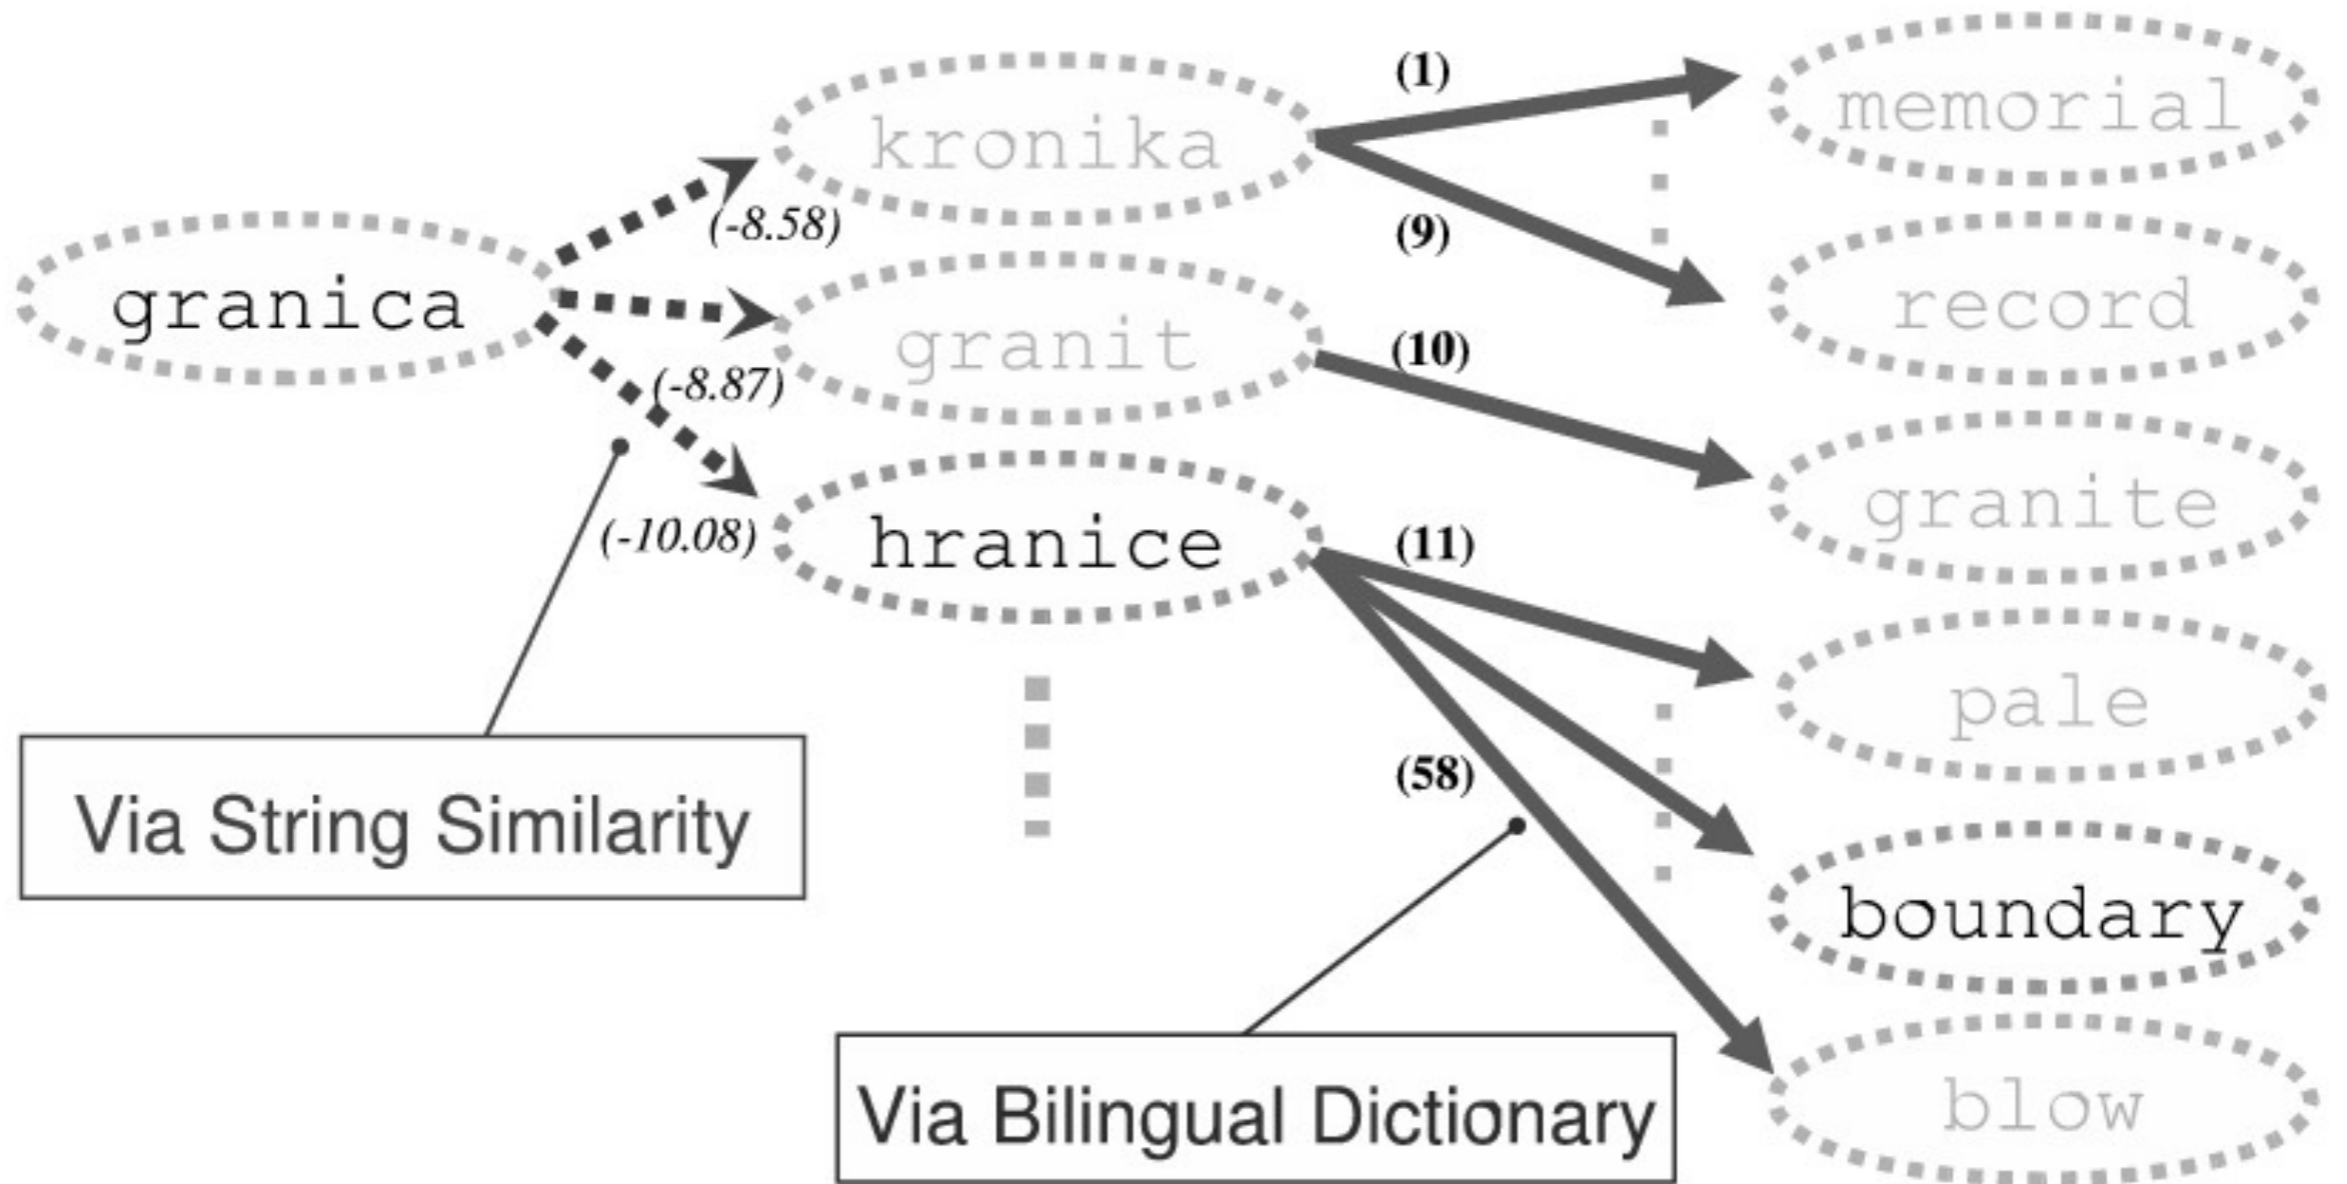

Solution: Use only monolingual corpora in source, target languages

- But use many information sources to propose and rank translation candidates

# Bridge Languages

# Similarity Measures

for re-ranking cognate/transliteration hypotheses

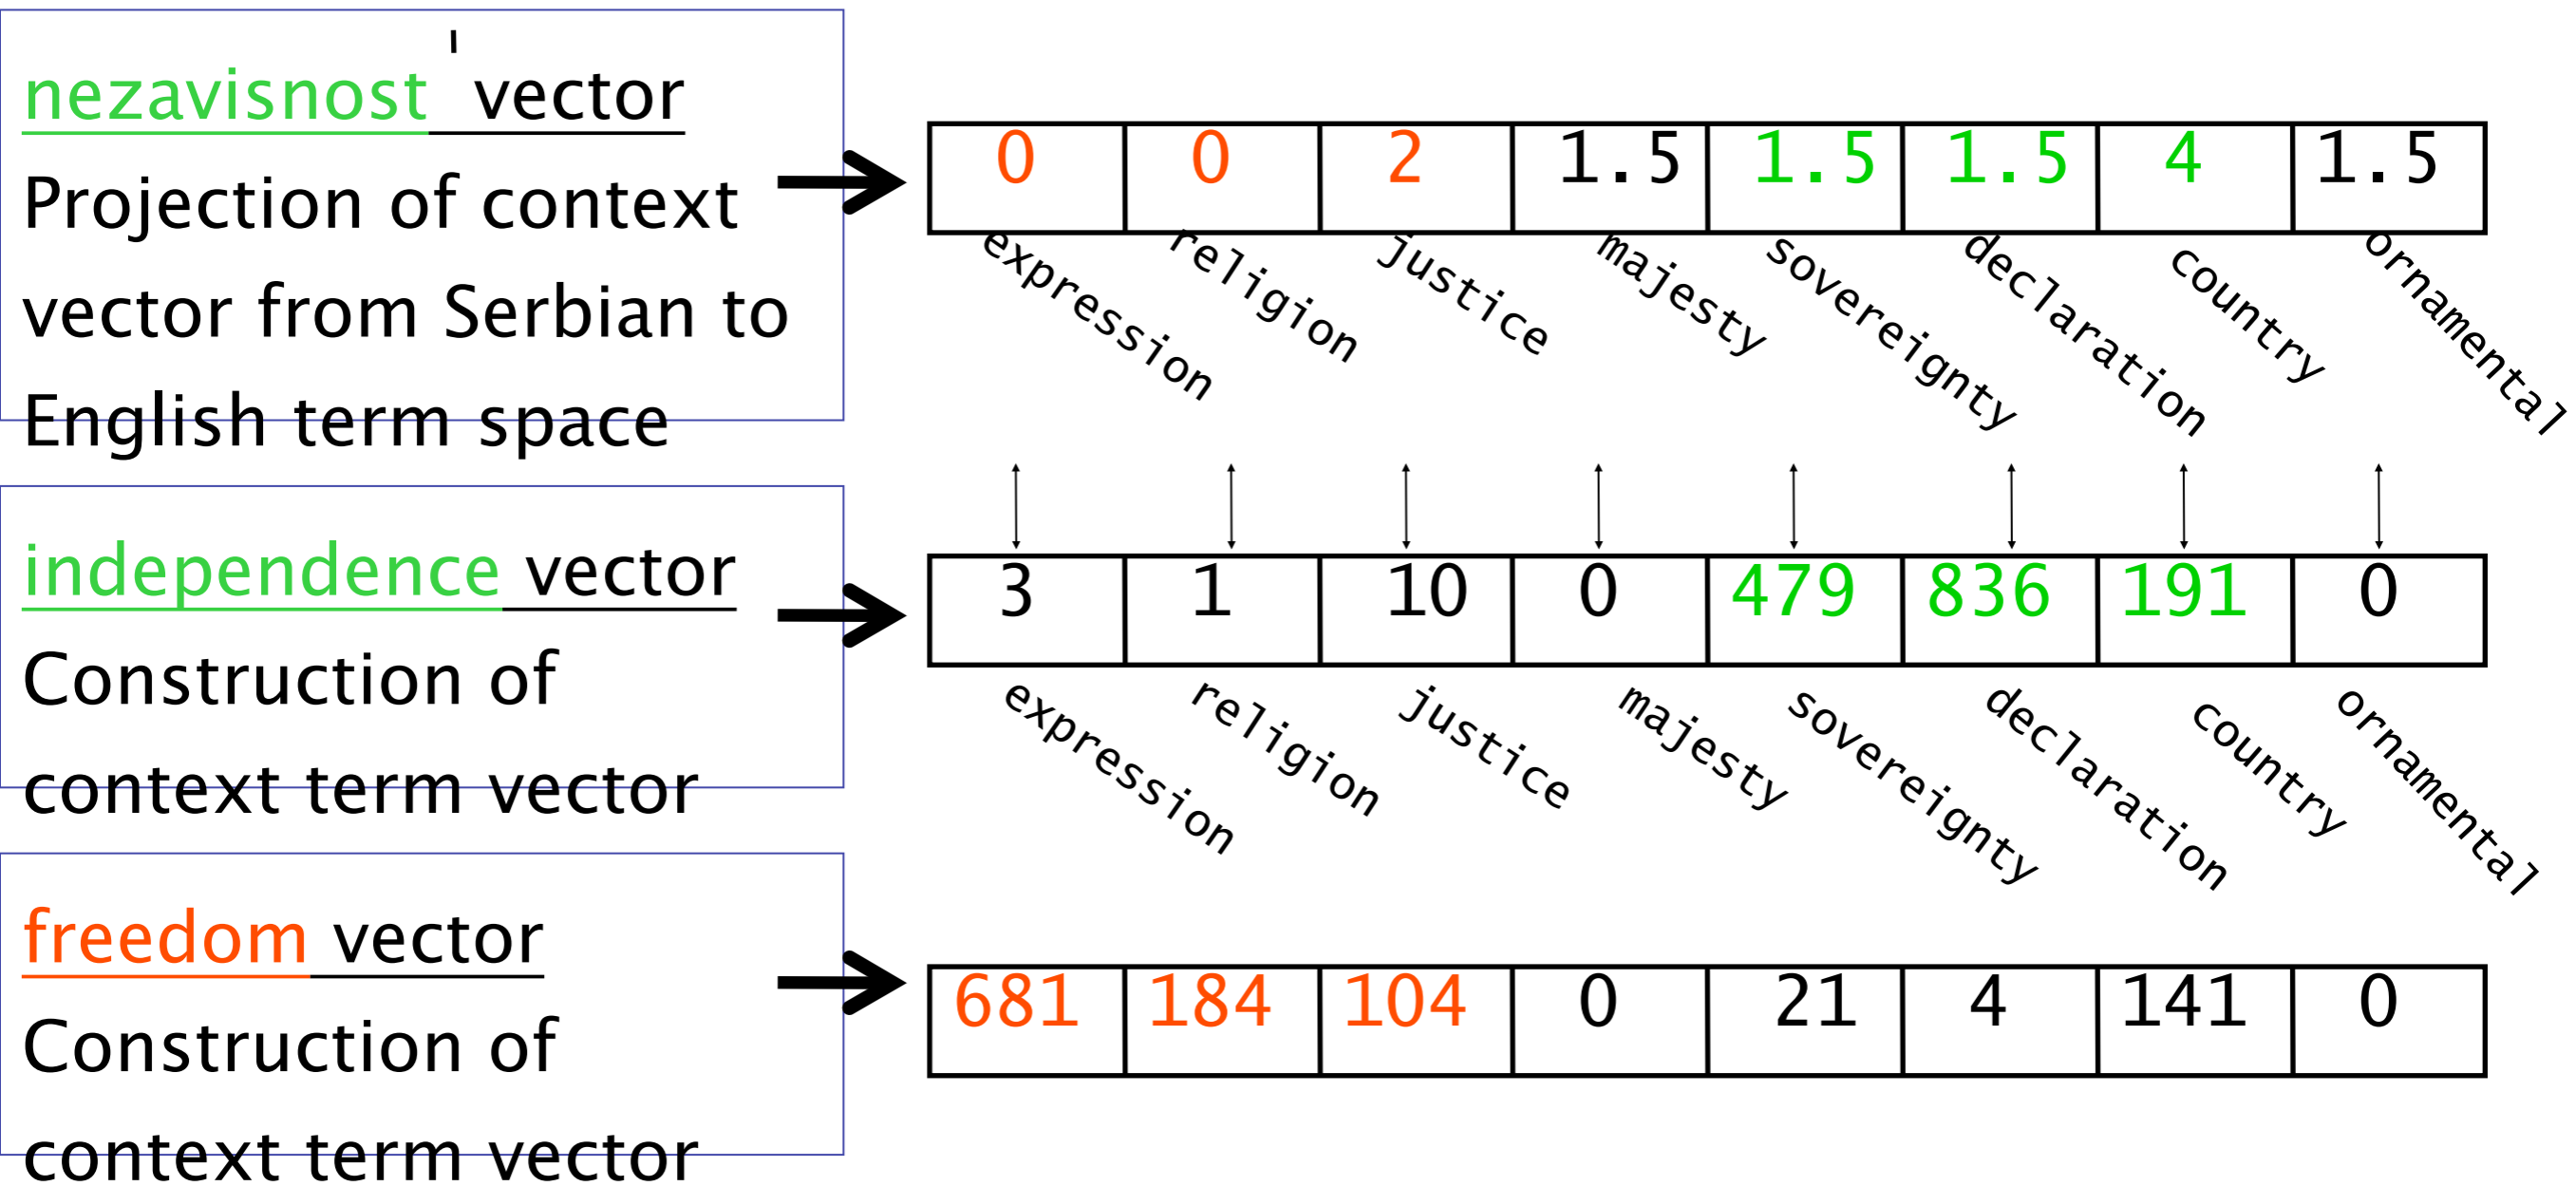

1. Probabilistic string transducers
2. Context similarity
3. Date distribution similarity
4. Similarities based on monolingual word properties

# Similarity Measures

1. Probabilistic string transducers
2. Context similarity
3. Date distribution similarity
4. Similarities based on monolingual word properties

# Compare Vectors

Compute cosine similarity between nezavisnost and “independence”  
... and between nezavisnost and “freedom”

# Similarity Measures

1. Probabilistic string transducers
2. Context similarity
3. Date distribution similarity
4. Similarities based on monolingual word properties

# Date Distribution Similarity

- Topical words associated with real-world events appear within news articles in bursts following the date of the event
- Synonymous topical words in different languages, then, display similar distributions across dates in news text: this can be measured
- We use cosine similarity on date term vectors, with term values  $p(\text{word} | \text{date})$ , to quantify this notion of similarity

# Date Distribution Similarity - Example

# Similarity Measures

1. Probabilistic string transducers
2. Context similarity
3. Date distribution similarity
4. Similarities based on monolingual word properties

# Relative Frequency

$$rf(w_F) = \frac{f_{C_F}(w_F)}{|C_F|}$$

$$rf(w_E) = \frac{f_{C_E}(w_E)}{|C_E|}$$

Cross-Language Comparison:

$$\min \left( \frac{rf(w_F)}{rf(w_E)}, \frac{rf(w_E)}{rf(w_F)} \right)$$

[min-ratio method]

Precedent in Yarowsky & Wicentowski (2000);  
used relative frequency similarity for  
morphological analysis

WASHINGTON (Reuters) - The United States created jobs at the fastest pace in nine months in January and the unemployment rate unexpectedly dropped to a near three-year low, giving a boost to President Barack Obama.

Nonfarm payrolls jumped 243,000, the Labor Department said on Friday, as factory jobs grew by the most in a year. The jobless rate fell to 8.3 percent - the lowest since February 2009 - from 8.5 percent in December.

The gain in employment was the largest since April and it far outstripped the 150,000 predicted in a Reuters poll of economists. It hinted at underlying economic strength and lessened chances of further stimulus from the Federal Reserve.

"More pistons in the economic engine have begun to fire, pointing to accelerating economic growth. One of the happiest persons reading this job report is President Obama," said Sung Won Sohn, an economics professor at California State University Channel Islands.

The payroll gains were widespread - from retail to temporary help, and from construction to manufacturing - an indication the recovery was becoming more durable.

# Multilingual Topical Similarity

## Abraham Lincoln

From Wikipedia, the free encyclopedia

*This article is about the American president. For other uses, see [Abraham Lincoln \(disambiguation\)](#).*

**Abraham Lincoln** <sup>i</sup>/ˈɛɪbrəhæm ˈlɪnkən/ (February 12, 1809 – April 15, 1865) was the **16th President of the United States**, serving from March 1861 until his **assassination** in April 1865. He successfully led his country through a great constitutional, military and moral crisis – the **American Civil War** – preserving the Union, while ending **slavery**, and promoting economic and financial modernization. Reared in a poor family on the western frontier, Lincoln was mostly self-educated. He became a country lawyer, an **Illinois state legislator**, and a one-term member of the **United States House of Representatives**, but failed in two attempts to be elected to the **United States Senate**.

## Abraham Lincoln

**Abraham Lincoln** <sup>i</sup>/ˈɛɪbrəhæm ˈlɪnkən/ (\* 12. Februar 1809 bei Hodgenville, **Hardin County**, heute: **LaRue County**, **Kentucky**; † 15. April 1865 in **Washington, D.C.**) amtierte von 1861 bis 1865 als **16. Präsident der Vereinigten Staaten** von Amerika. Er war der erste aus den Reihen der **Republikanischen Partei** und der erste, der einem **Attentat** zum Opfer fiel. 1860 gewählt, gelang ihm 1864 die **Wiederwahl**.

Seine **Präsidentschaft** gilt als eine der bedeutendsten in der **Geschichte der Vereinigten Staaten**: Die Wahl des **Sklavereieigners** veranlasste zunächst sieben, später weitere vier der **sklavenhaltenden Südstaaten** zur **Sezession**. Lincoln führte die verbliebenen **Nordstaaten** durch den daraus entstandenen **Bürgerkrieg**, setzte die **Wiederherstellung der Union** durch und betrieb erfolgreich die **Abschaffung der Sklaverei in den Vereinigten Staaten**. Unter seiner Regierung schlugen die USA den Weg zum **zentral regierten, modernen Industriestaat** ein und schufen so die Basis für ihren **Aufstieg zur Weltmacht** im 20. Jahrhundert.

## Abraham Lincoln

From Wikipedia, the free encyclopedia

*This article is about the American president. For other uses, see [Abraham Lincoln \(disambiguation\)](#).*

**Abraham Lincoln** <sup>i</sup>/ˈɛɪbrəhæm ˈlɪnkən/ (February 12, 1809 – April 15, 1865) was the **16th President of the United States**, serving from March 1861 until his **assassination** in April 1865. He successfully led his country through a great constitutional, military and moral crisis – the **American Civil War** – preserving the Union, while ending **slavery**, and promoting economic and financial modernization. Reared in a poor family on the western frontier, Lincoln was mostly self-educated. He became a country lawyer, an **Illinois state legislator**, and a one-term member of the **United States House of Representatives**, but failed in two attempts to be elected to the **United States Senate**.

## Abraham Lincoln

**Abraham Lincoln** [<sup>i</sup>/ɛɪbrəhæm ˈlɪnkən/] (\* 12. Februar 1809 bei Hodgenville, **Hardin County**, heute: **LaRue County**, **Kentucky**; † 15. April 1865 in **Washington, D.C.**) amtierte von 1861 bis 1865 als **16. Präsident der Vereinigten Staaten** von **Amerika**. Er war der erste aus den Reihen der **Republikanischen Partei** und der erste, der einem **Attentat** zum Opfer fiel. 1860 gewählt, gelang ihm 1864 die **Wiederwahl**.

Seine **Präsidentschaft** gilt als eine der bedeutendsten in der **Geschichte der Vereinigten Staaten**: Die Wahl des **Sklavereieigners** veranlasste zunächst sieben, später weitere vier der **sklavenhaltenden Südstaaten** zur **Sezession**. Lincoln führte die verbliebenen **Nordstaaten** durch den daraus entstandenen **Bürgerkrieg**, setzte die **Wiederherstellung der Union** durch und betrieb erfolgreich die **Abschaffung der Sklaverei in den Vereinigten Staaten**. Unter seiner Regierung schlugen die **USA** den Weg zum **zentral regierten, modernen Industriestaat** ein und schufen so die **Basis für ihren Aufstieg zur Weltmacht** im 20. Jahrhundert.

# Search

What's the best translation  
(under our model)?

# Search

- Even if we know the right words in a translation, there are  $n!$  permutations.  
 $10! = 3,626,800$        $20! \approx 2.43 \times 10^{18}$        $30! \approx 2.65 \times 10^{32}$
- We want the translation that gets the highest score under our model
  - Or the best  $k$  translations
  - Or a random sample from the model's distribution
- But **not** in  $n!$  time!

*We could declare these equivalent.*

etc., u.s.w., until all source words are covered

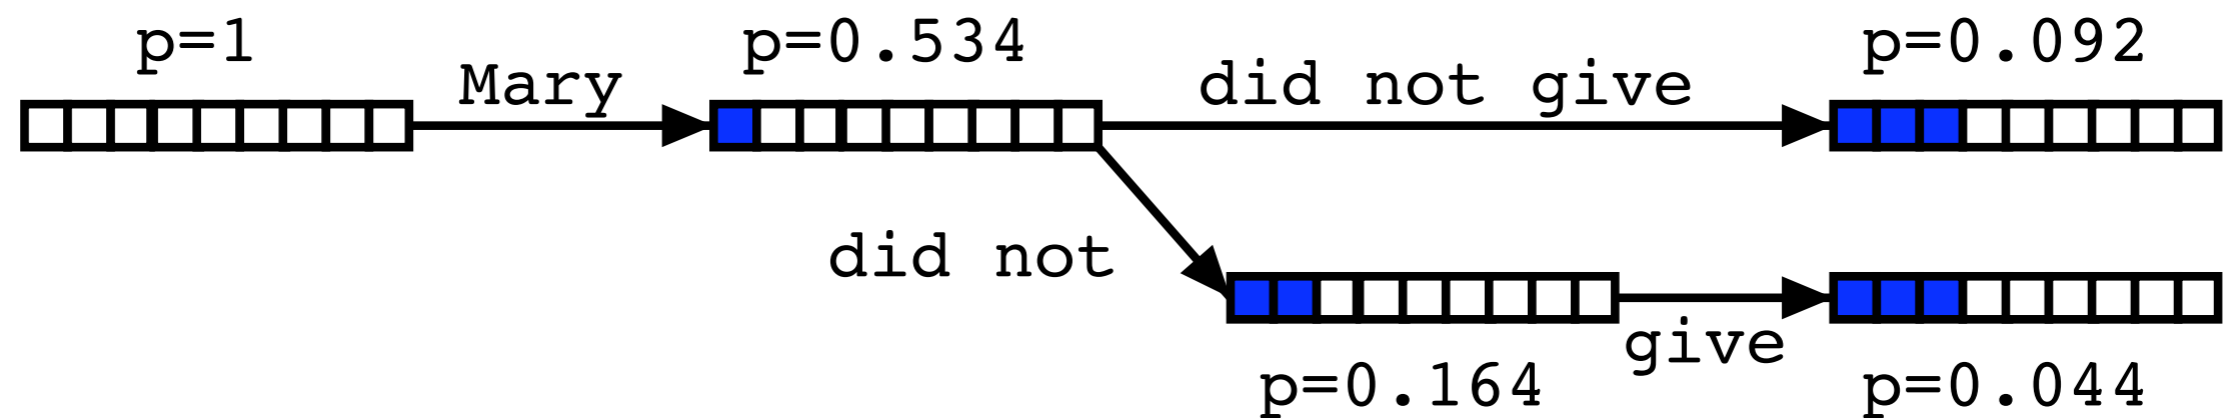

# Search in Phrase Models

- Many ways of segmenting source
- Many ways of translating each segment
- *Restrict* model class: phrases  $>$ , e.g., 7 words, no long-distance reordering
- *Recombine* equivalent hypotheses
- *Prune* away unpromising partial translations or we'll run out of space and/or run too long
  - How to compare partial translations?
  - Some start with easy stuff: “in”, “das”, ...
  - Some with hard stuff: “Agrarpolitik”, “Entscheidungsproblem”, ...

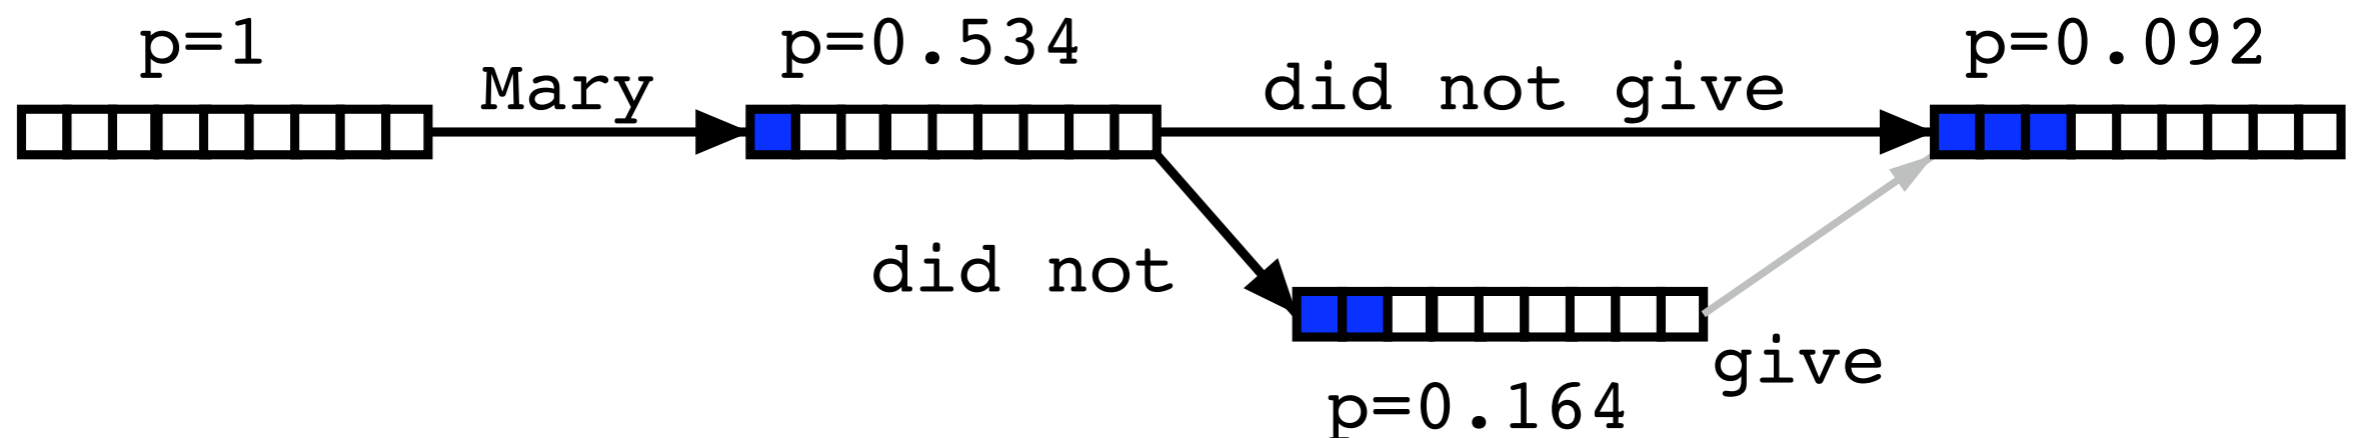

# Hypothesis Recombination

- Different paths to the same partial translation

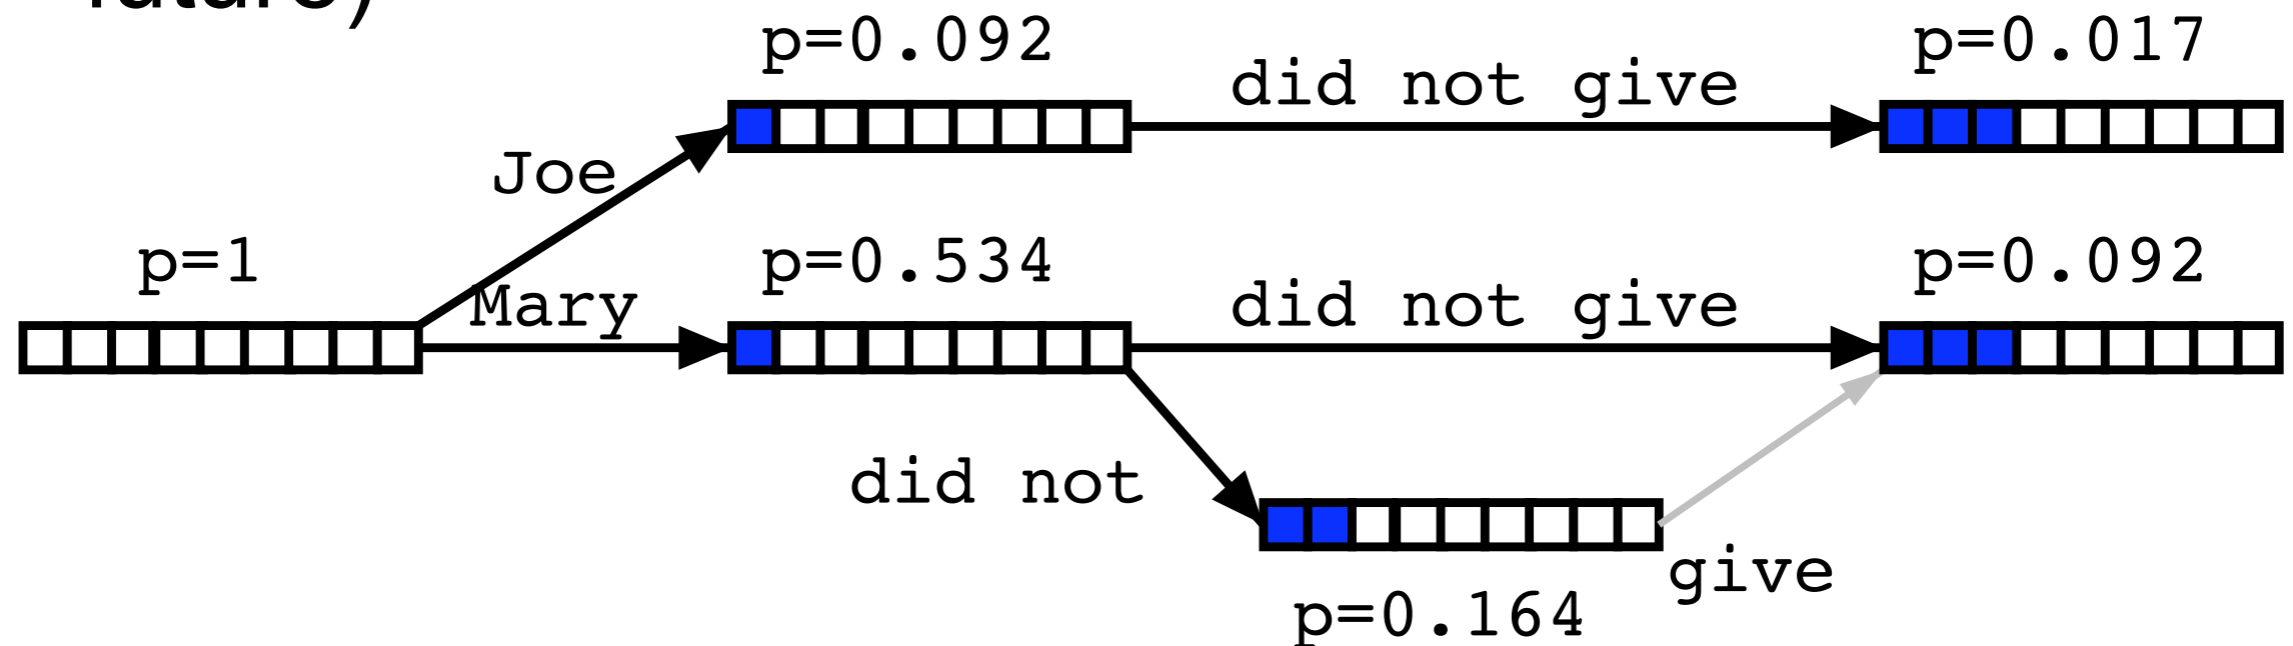

# Hypothesis Recombination

- Different paths to the same partial translation
- Combine paths
  - Drop weaker path
  - Keep backpointer to weaker path (for lattice or n-best generation)

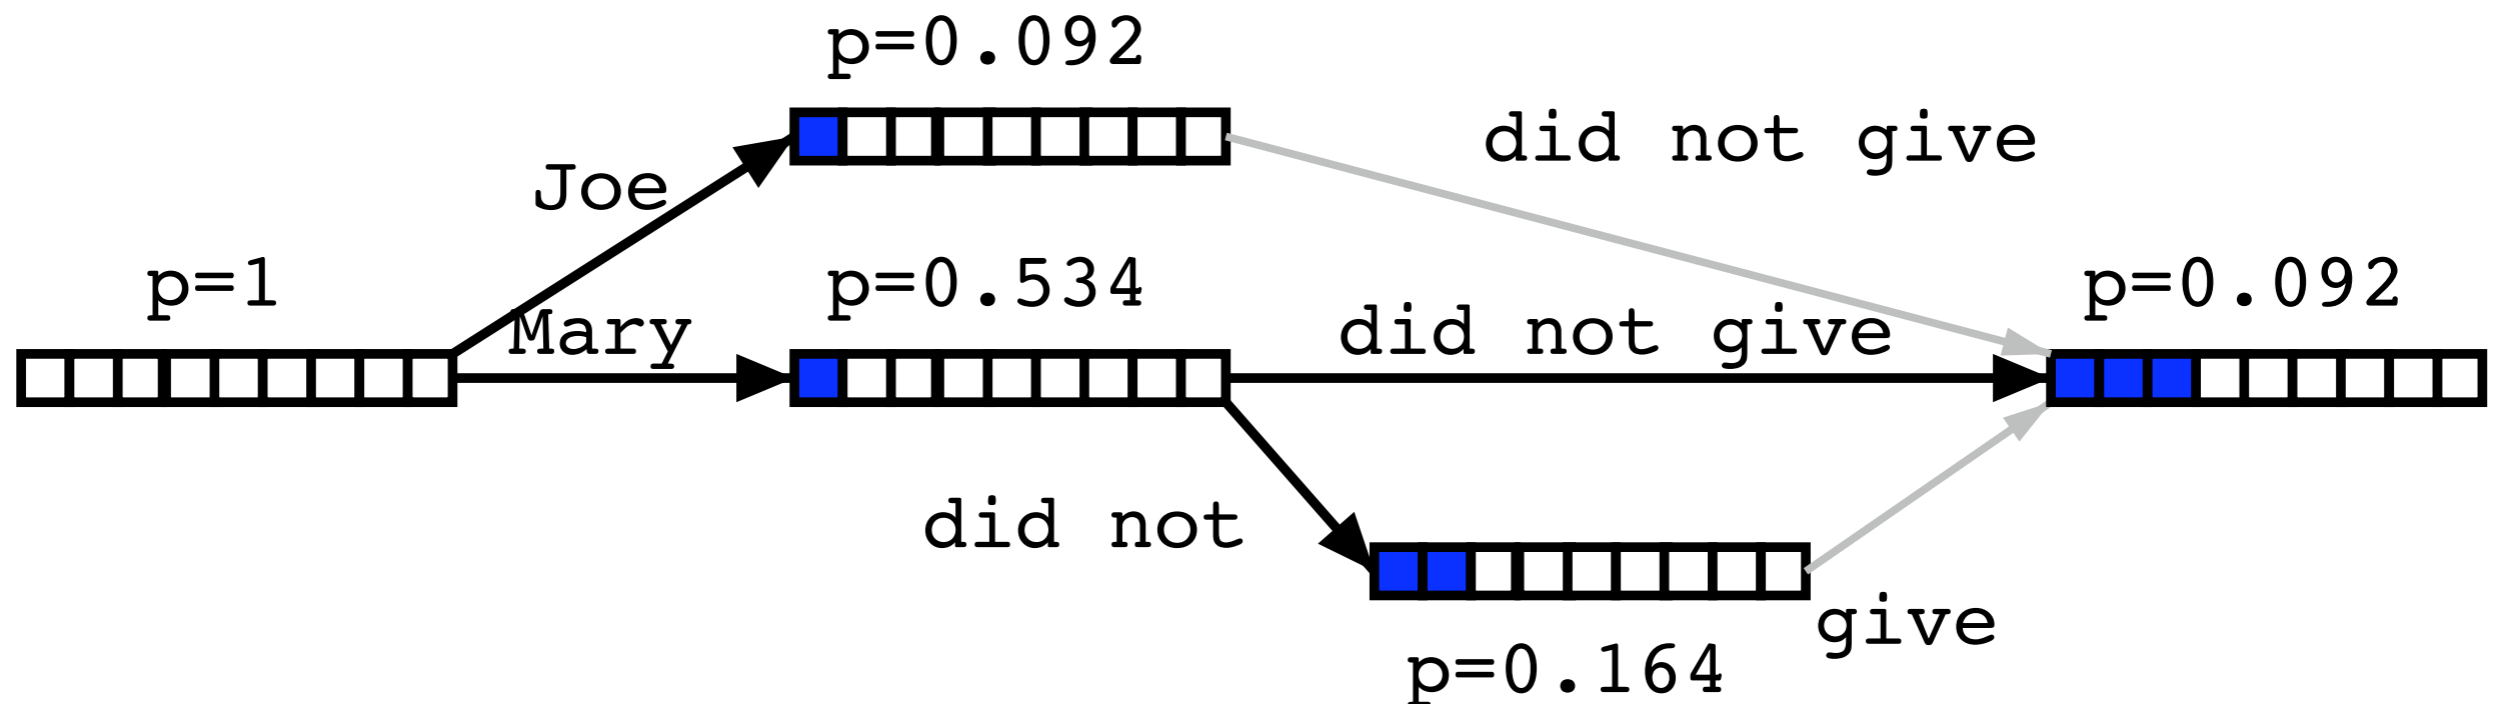

# Hypothesis Recombination

- Recombined hypotheses do not have to match completely
- Weaker path can be dropped if
  - Last  $n$  target words match (for  $n+1$ -gram lang. model)
  - Source coverage vectors match (same best future)

# Hypothesis Recombination

- Combining partially matching hypotheses

## Pruning

- Hypothesis recombination is *not sufficient*

Heuristically *discard* weak hypotheses early

- Organize Hypothesis in **stacks**, e.g. by
  - *same* foreign words covered
  - *same number* of foreign words covered
  - *same number* of English words produced
- Compare hypotheses in stacks, discard bad ones
  - **histogram pruning**: keep top  $n$  hypotheses in each stack (e.g.,  $n=100$ )
  - **threshold pruning**: keep hypotheses that are at most  $\epsilon$  times the cost of best hypothesis in stack (e.g.,  $\epsilon = 0.001$ )

# Word Lattice Generation

- **Search graph** can be easily converted into a **word lattice**
  - can be further mined for **n-best lists**
  - enables **reranking** approaches
  - enables **discriminative training**

## Hypothesis Stacks

- Organization of hypothesis into stacks
  - here: based on *number of foreign words* translated
  - during translation all hypotheses from one stack are expanded
  - expanded Hypotheses are placed into stacks

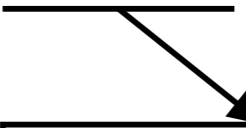

## Limits on Reordering

- Reordering may be **limited**
  - **Monotone** Translation: No reordering at all
  - Only phrase movements of at most  $n$  words
- Reordering limits *speed* up search (polynomial instead of exponential)
- Current reordering models are weak, so limits *improve* translation quality

## Comparing Hypotheses

- Comparing hypotheses with *same number of foreign words* covered

Maria no      dio una bofetada      a la      bruja verde

  
 e: Mary did not  
 f: \*\*-----  
 p: 0.154

**better**  
**partial**  
**translation**

  
 e: the  
 f: -----\*\*--  
 p: 0.354

**covers**  
**easier part**  
**--> lower cost**

- Hypothesis that covers *easy part* of sentence is preferred  
 Need to consider **future cost** of uncovered parts  
**or:** have one hypothesis stack per coverage vector

# Synchronous Grammars

- Just like monolingual grammars except...
  - Each rule involves pairs (tuples) of nonterminals
  - Tuples of elementary trees for TAG, etc.
- First proposed for source-source translation in compilers
- Can be constituency, dependency, lexicalized, etc.
- Parsing speedups for monolingual grammar don't necessarily work
  - E.g., no split-head trick for lexicalized parsing
- Binarization less straightforward

# Bilingual Parsing

# MT as Parsing

- If we only have the source, parse it while recording all compatible target language trees.
- Runtime is also multiplied by a *grammar constant*: one string could be a noun and a verb phrase
- Continuing problem of multiple hidden configurations (trees, instead of phrases) for one translation.

# Parsing as Deduction

$$\forall A, B, C \in N, W \in V, 0 \leq i, j, k \leq m$$

$$\text{constit}(B, i, j) \wedge \text{constit}(C, j, k) \wedge A \rightarrow BC \Rightarrow \text{constit}(A, i, k)$$

$$\text{word}(W, i) \wedge A \rightarrow W \Rightarrow \text{constit}(A, i, i + 1)$$

$$\text{constit}(A, i, k) = \bigvee_{B, C, j} \text{constit}(B, i, j) \wedge \text{constit}(C, j, k) \wedge A \rightarrow B C$$

$$\text{constit}(A, i, j) = \bigvee_W \text{word}(W, i, j) \wedge A \rightarrow W$$

# Parsing as Deduction

$$\mathit{constit}(A, i, k) = \bigvee_{B, C, j} \mathit{constit}(B, i, j) \wedge \mathit{constit}(C, j, k) \wedge A \rightarrow B C$$

$$\mathit{constit}(A, i, j) = \bigvee_W \mathit{word}(W, i, j) \wedge A \rightarrow W$$

$$\begin{aligned} \mathit{score}(\mathit{constit}(A, i, k)) &= \max_{B, C, j} \mathit{score}(\mathit{constit}(B, i, j)) \\ &\quad \cdot \mathit{score}(\mathit{constit}(C, j, k)) \\ &\quad \cdot \mathit{score}(A \rightarrow B C) \end{aligned}$$

$$\mathit{score}(\mathit{constit}(A, i, j)) = \max_W \mathit{score}(\mathit{word}(W, i, j)) \cdot \mathit{score}(A \rightarrow W)$$

And how about the inside algorithm?

# Bilingual Parsing: ITG

$$s(X, i, k, u, w) = \bigvee_{j, v, Y, Z} s(Y, i, j, u, v) \wedge s(Z, j, k, v, w) \wedge [X \rightarrow Y Z]$$

$$s(X, i, k, u, w) = \bigvee_{j, v, Y, Z} s(Y, i, j, v, w) \wedge s(Z, j, k, u, v) \wedge \langle X \rightarrow Y Z \rangle$$

$$s(X, i, j, u, v) = w(S, i, j) \wedge w(T, u, v) \wedge X \rightarrow S/T$$

$$s(X, i, j, u, u) = w(S, i, j) \wedge X \rightarrow S/\epsilon$$

$$s(X, i, i, u, v) = w(T, u, v) \wedge X \rightarrow \epsilon/T$$

**Similar extensions for finding the best alignment or the expectations of particular alignments**

# What Makes Search Hard?

- What we really want: the best (highest-scoring) translation
- What we get: the best translation/phrase segmentation/alignment
  - Even summing over all ways of segmenting *one* translation is hard.
- Most common approaches:
  - Ignore problem
  - Sum over top  $j$  translation/segmentation/alignment triples to get top  $k \ll j$  translations

# Redundancy in $n$ -best Lists

# Training

Which features of data predict good translations?

# Training: Generative/Discriminative

- Generative
  - Maximum likelihood training:  $\max p(\text{data})$
  - “Count and normalize”
  - Maximum likelihood with hidden structure
    - Expectation Maximization (EM)
- Discriminative training
  - Maximum conditional likelihood
  - Minimum error/risk training
  - Other criteria: perceptron and max. margin

# “Count and Normalize”

- Language modeling example: assume the probability of a word depends only on the previous 2 words.

$$p(\text{disease} | \text{into the}) = \frac{p(\text{into the disease})}{p(\text{into the})}$$

- $p(\text{disease} | \text{into the}) = 3/20 = 0.15$
- “Smoothing” reflects a prior belief that  $p(\text{breach} | \text{into the}) > 0$  despite these 20 examples.

this									
question									
	Auf	diese	Frage	habe	ich	leider	keine	Antwort	bekommen

Some good phrase pairs.

# Phrase Models

I								
did								
not								
unfortunately								
receive								
an								
answer								
to								
this								
question								
	Auf	diese	Frage	habe	ich	leider	keine	Antwort bekommen

Some bad phrase pairs.

# “Count and Normalize”

- Usual approach: treat relative frequencies of source phrase  $s$  and target phrase  $t$  as probabilities

$$p(s | t) \equiv \frac{\textit{count}(s, t)}{\textit{count}(t)} \quad p(t | s) \equiv \frac{\textit{count}(s, t)}{\textit{count}(s)}$$

- This leads to overcounting when not all segmentations are legal due to unaligned words.

# Hidden Structure

- But really, we don't observe word alignments.
- How are word alignment model parameters estimated?
- Find (all) structures consistent with observed data.
  - Some links are incompatible with others.
  - We need to score complete sets of links.

# Hidden Structure and EM

- Expectation Maximization
  - Initialize model parameters (randomly, by some simpler model, or otherwise)
  - Calculate probabilities of hidden structures
  - Adjust parameters to maximize likelihood of observed data given hidden data
  - Iterate
- Summing over *all* hidden structures can be expensive
  - Sum over 1-best,  $k$ -best, other sampling methods

# Discriminative Training

- Given a source sentence, give “good” translations a higher score than “bad” translations.
- We care about good translations, not a high probability of the training data.
- Spend less “energy” modeling bad translations.
- Disadvantages
  - We need to run the translation system at each training step.
  - System is tuned for one task (e.g. translation) and can’t be directly used for others (e.g. alignment)

# “Good” Compared to What?

- Compare current translation to
- Idea #1: a human translation. OK, but
  - Good translations can be very dissimilar
  - We’d need to find hidden features (e.g. alignments)
- Idea #2: other top  $n$  translations (the “n-best list”). Better in practice, but
  - Many entries in n-best list are the same apart from hidden links
- Compare with a **loss function  $L$** 
  - 0/1: wrong or right; equal to reference or not
  - Task-specific metrics (word error rate, BLEU, ...)

# MT Evaluation

## \* Intrinsic

**Human evaluation**

**Automatic (machine) evaluation**

## \* Extrinsic

**How useful is MT system output for...**

**Deciding whether a foreign language blog is about politics?**

**Cross-language information retrieval?**

**Flagging news stories about terrorist attacks?**

**...**

# Human Evaluation

**Je suis fatigué.**

**Tired is I.**

**Cookies taste good!**

**I am exhausted.**

<b>Adequacy</b>	<b>Fluency</b>
<b>5</b>	<b>2</b>
<b>1</b>	<b>5</b>
<b>5</b>	<b>5</b>

# Human Evaluation

## **PRO**

**High quality**

## **CON**

**Expensive!**

**Person (preferably bilingual) must make a time-consuming judgment per system hypothesis.**

**Expense prohibits frequent evaluation of incremental system modifications.**

# Automatic Evaluation

## **PRO**

**Cheap. Given available reference translations, free thereafter.**

## **CON**

**We can only measure some proxy for translation quality.  
(Such as N-Gram overlap or edit distance).**

# Output of Chinese-English system

## **In the First Two Months Guangdong's Export of High-Tech Products 3.76 Billion US Dollars**

Xinhua News Agency, Guangzhou, March 16 (Reporter Chen Jizhong) - The latest statistics show that between January and February this year, Guangdong's export of high-tech products 3.76 billion US dollars, with a growth of 34.8% and accounted for the province's total export value of 25.5%. The export of high-tech products bright spots frequently now, the Guangdong provincial foreign trade and economic growth has made important contributions. Last year, Guangdong's export of high-tech products 22.294 billion US dollars, with a growth of 31 percent, an increase higher than the province's total export growth rate of 27.2 percent; exports of high-tech products net increase 5.270 billion us dollars, up for the traditional labor-intensive products as a result of prices to drop from the value of domestic exports decreased.

## **In the Suicide explosion in Jerusalem**

Xinhua News Agency, Jerusalem, March 17 (Reporter bell tsui flower nie Xiaoyang) - A man on the afternoon of 17 in Jerusalem in the northern part of the residents of rammed a bus near ignition of carry bomb, the wrongdoers in red-handed was killed and another nine people were slightly injured and sent to hospital for medical treatment.

# Partially excellent translations

## Evaluation of Machine Translation Systems

### **Bleu (Papineni, Roukos, Ward and Zhu, 2002):**

Candidate 1: It is a guide to action which ensures that the military always obeys the commands of the party.

Candidate 2: It is to insure the troops forever hearing the activity guidebook that party direct.

Reference 1: It is a guide to action that ensures that the military will forever heed Party commands.

Reference 2: It is the guiding principle which guarantees the military forces always being under the command of the Party.

Reference 3: It is the practical guide for the army always to heed the directions of the party.

## Unigram Precision

- **Unigram Precision** of a candidate translation:

$$\frac{C}{N}$$

where  $N$  is number of words in the candidate,  $C$  is the number of words in the candidate which are in at least one reference translation.

e.g.,

Candidate 1: It is a guide to action which ensures that the military always obeys the commands of the party.

$$Precision = \frac{17}{18}$$

(only *obeys* is missing from all reference translations)

## Modified Unigram Precision

- Problem with unigram precision:

Candidate: the the the the the the the

Reference 1: the cat sat on the mat

Reference 2: there is a cat on the mat

precision =  $7/7 = 1???$

- **Modified unigram precision: “Clipping”**

- Each word has a “cap”. e.g.,  $cap(the) = 2$
- A candidate word  $w$  can only be correct a maximum of  $cap(w)$  times. e.g., in candidate above,  $cap(the) = 2$ , and  $the$  is correct twice in the candidate  $\Rightarrow$

$$Precision = \frac{2}{7}$$

## Modified N-gram Precision

- Can generalize modified unigram precision to other n-grams.
- For example, for candidates 1 and 2 above:

$$Precision_1(\text{bigram}) = \frac{10}{17}$$

$$Precision_2(\text{bigram}) = \frac{1}{13}$$

## Precision Alone Isn't Enough

Candidate 1: **of the**

Reference 1: It is a guide to action that ensures that the military will forever heed Party commands.

Reference 2: It is the guiding principle which guarantees the military forces always being under the command of the Party.

Reference 3: It is the practical guide for the army always to heed the directions of the party.

$$Precision(unigram) = 1$$

$$Precision(bigram) = 1$$

## But Recall isn't Useful in this Case

- Standard measure used in addition to precision is **recall**:

$$Recall = \frac{C}{N}$$

where  $C$  is number of n-grams in candidate that are correct,  $N$  is number of words in the references.

Candidate 1: I always invariably perpetually do.

Candidate 2: I always do

Reference 1: I always do

Reference 1: I invariably do

Reference 1: I perpetually do

## Sentence Brevity Penalty

- Step 1: for each candidate, compute closest matching reference (in terms of length)  
e.g., our candidate is length 12, references are length 12, 15, 17. Best match is of length 12.
- Step 2: Say  $l_i$  is the length of the  $i$ 'th candidate,  $r_i$  is length of best match for the  $i$ 'th candidate, then compute

$$brevity = \frac{\sum_i r_i}{\sum_i l_i}$$

(I think! from the Papineni paper, although  $brevity = \frac{\sum_i r_i}{\sum_i \min(l_i, r_i)}$  might make more sense?)

- Step 3: compute brevity penalty

$$BP = \begin{cases} 1 & \text{If } brevity < 1 \\ e^{1-brevity} & \text{If } brevity \geq 1 \end{cases}$$

e.g., if  $r_i = 1.1 \times l_i$  for all  $i$  (candidates are always 10% too short) then  
 $BP = e^{-0.1} = 0.905$

## The Final Score

- Corpus precision for any n-gram is

$$p_n = \frac{\sum_{C \in \{Candidate\}} \sum_{ngram \in C} Count_{clip}(ngram)}{\sum_{C \in \{Candidate\}} \sum_{ngram \in C} Count(ngram)}$$

i.e. number of correct ngrams in the candidates (after “clipping”) divided by total number of ngrams in the candidates

- Final score is then

$$Bleu = BP \times (p_1 p_2 p_3 p_4)^{1/4}$$

i.e.,  $BP$  multiplied by the geometric mean of the unigram, bigram, trigram, and four-gram precisions

## Automatic Evaluation: Bleu Score

**hypothesis 1**      **I am exhausted**

**hypothesis 2**      **Tired is I**

**reference 1**        **I am tired**

**reference 2**        **I am ready to sleep now**

# How Good are Automatic Metrics?

slide from G. Doddington (NIST)

# Correlation? [Callison-Burch et al., 2006]

## ● DARPA/NIST MT Eval 2005

[from Callison-Burch et al., 2006, EACL]

- Mostly statistical systems (all but one in graphs)
- One submission **manual post-edit** of statistical system's output
- Good adequacy/fluency scores *not reflected* by BLEU

# Correlation? [Callison-Burch et al., 2006]

- Comparison of

[from Callison-Burch et al., 2006, EACL]

- *good statistical* system: **high** BLEU, **high** adequacy/fluency
- *bad statistical* sys. (trained on less data): **low** BLEU, **low** adequacy/fluency
- *Systran*: **lowest** BLEU score, but **high** adequacy/fluency

# How Good are Automatic Metrics?

- Do n-gram methods like BLEU overly favor certain types of systems?
- Automatic metrics still useful
- During development of one system, a better BLEU indicates a better system
- Evaluating different systems has to depend on human judgement
- What are some other evaluation ideas?

# Minimizing Error/Maximizing Bleu

- Adjust parameters to minimize error ( $L$ ) when translating a training set
- Error as a function of parameters is
  - *nonconvex*: not guaranteed to find optimum
  - *piecewise constant*: slight changes in parameters might not change the output.
- Usual method: optimize one parameter at a time with linear programming

# Generative/Discriminative Reunion

- Generative models can be cheap to train: “count and normalize” when nothing’s hidden.
- Discriminative models focus on problem: “get better translations”.
- Popular combination
  - Estimate several generative translation and language models using relative frequencies.
  - Find their optimal (log-linear) combination using discriminative techniques.

# Generative/Discriminative Reunion

Score each hypothesis with several generative models:

$$\theta_1 p_{phrase}(\bar{s} | \bar{t}) + \theta_2 p_{phrase}(\bar{t} | \bar{s}) + \theta_3 p_{lexical}(s | t) + \mathbf{L} + \theta_7 p_{LM}(\bar{t}) + \theta_8 \# \text{ words} + \mathbf{L}$$

If necessary, renormalize into a probability distribution:

$$Z = \sum_k \exp(\mathbf{e} \cdot \mathbf{f}_k)$$

*Unnecessary if thetas sum to 1 and p's are all probabilities.*

where  $k$  ranges over all hypotheses. We then have

$$p(t_i | s) = \frac{1}{Z} \exp(\mathbf{e} \cdot \mathbf{f})$$

*Exponentiation makes it positive.*

for any given hypothesis  $i$ .

# Minimizing Risk

Instead of the error of the 1-best translation, compute **expected error** (risk) using  $k$ -best translations; this makes the function differentiable.

Smooth probability estimates using gamma to even out local bumpiness. Gradually increase gamma to approach the 1-best error.

$$E_{p_{\gamma, \theta}} [L(s, t)]$$

$$p_{\gamma, \theta}(t_i | s_i) = \frac{[\exp \theta \cdot \mathbf{f}_i]^\gamma}{\sum_{k'} [\exp \theta \cdot \mathbf{f}_{k'}]^\gamma}$$

$\gamma = 0.1$

$\gamma = 1$

$\gamma = 10$

$\gamma = \infty$
